In dogs, homoplastic grafts of the right lateral lobe and the right dorsal segment of the donor's liver proved fatal within 1-9 days, with significant vascular congestion developing within 48 hr. The technic was adjudged unsatisfactory for study of the immunologic problems involved in hepatic transplant. Following orthotopic transplant into hepatectomized dogs, without immunosuppressive therapy, normal levels of prothrombin and its cofactors were re-established temporarily, as was normal inhibition of fibrinolytic activity, prior to the onset of delayed immunologic response and rejection of the graft. Similar orthotopic transplants were then supplemented by splenectomy and immunosuppressive therapy with azathioprine under antibiotic cover or by azathioprine plus intermittent, postoperative admin. of actinomycin C under similar conditions. The value of splenectomy was considered questionable in both cases. Azathioprine alone prolonged survival time in a few animals but was unable to delay the beginning of spontaneous rejection of the graft which was demonstrable from the start of the second wk. in all dogs not dying prematurely of intercurrent complications. It was accompanied by progressive development of hepatic insufficiency. Postoperative association of actinomycin C appeared to inhibit spontaneous rejection of the graft in dogs which did not die of early, intercurrent complications. However, it engendered sufficient toxic reactions, in its own right, to have no significant effect on survival times.

- 9236 NORMAL HUMAN IRON STORAGE AND ITS RELATION TO ETHANOL CONSUMPTION. (E.) Powell, L. W. (U. Queensland Brisbane Hosp., Australia). *Aust. Ann. Med.* 15(2):110-115, 1966.

A significant difference in hepatic iron conc. and total hepatic iron content was found between subjects with heavy alcohol consumption and subjects with light alcohol consumption. These estimates were made on 100 subjects (ages from 15-90 yr) who had suffered sudden unexpected death and whose post-mortem examination revealed no abnormality. When those subjects with a heavy alcohol consumption (500 g of ethyl alcohol/wk.) were excluded from the calculations, the range of hepatic iron conc. was 0.03-0.53 per g wet wt. of liver which corresponded to a mild degree of hemosiderin deposition in histological preparations stained for iron. Thus, it is concluded that reported findings of stainable iron in the livers of relatives of patients with idiopathic hemochromatosis cannot be regarded as positive evidence of existence of the genetic abnormality unless the iron is present in increased amounts and unless alcoholism has been excluded.

- 9237 SELECTION OF PATIENTS FOR PORTAL-SYSTEMIC SHUNTS. (E.) Hermann, R. E. (Cleveland Clin. Found., Ohio), A. E. Rodriguez and L. J. McCormack. *J.A.M.A.* 196(12):1039-1044, 1966.

Portal hypertension is best relieved by a portal systemic shunt decompression of which portacaval shunt appears to be the most effective. Due to the high rate of mortality and morbidity, the proper selection of patients and reduction of surgical risk are essential to achieve max. survival and benefit. Of the 76 shunt procedure performed at the Cleveland Clinic during the past 17 yr., the indication was bleeding from esophageal varices in 59 patients and intractable ascites in another 11 patients. The overall mortality within 30 days of operation was 26%; an additional 15% died during the first yr. after surgery. A 5-yr. survival rate was observed in 45%. The major cause of postoperative death was progressive hepatic failure, with gastrointestinal bleeding next. The factors that influence mortality and morbidity are poor hepatic functional risk, urgent instead of elective performance of shunt procedure, increasing age of patient, and the pathological type of cirrhosis. In a selected group of patients under 55 yr. of age with cirrhosis of the

er and good hepatic function and in whom elective portacaval shunt was performed, 30-day postoperative mortality was only 12%, less than 50% that of the entire series of patients.

- 8 ACTIVITY OF AMINO-LAEVULINIC ACID SYNTHETASE IN NORMAL AND PORPHYRIC HUMAN LIVERS. (E.) Nakao, K. (U. Tokyo), O. Wada, T. Kitamura and K. Uono. *Nature (London)* 210(5038):838-839, 1966.

porphyrin metabolism was studied in a 32-year-old man with a 3-yr. history of acute intermittent porphyria who continued to excrete approx. 200 μ M of porphobilinogen and 80 μ M of delta aminolevulinic acid (II) while hospitalized during remission. synthetase was assayed by the Granick-Urata method, II-dehydrase and I-ase by Granick-Mauzerall method, and iron-protoporphyrin-chelatase (III) by the Labbe method. II-synthetase activity in porphyric liver mitochondria was markedly greater than in normal controls, II-dehydrase activity was approx. 2 times that of controls, I-ase and III were normal. The porphyric liver's ability to convert I to porphyrins was about twice that of controls. It would appear that the principal feature in acute intermittent porphyria is the overproduction of porphyrin precursors resulting from increased II-synthetase activity.

- 9 TISSUE ANTIBODIES IN PRIMARY BILIARY CIRRHOSIS, ACTIVE CHRONIC (LUPOID) HEPATITIS, CRYPTOGENIC CIRRHOSIS AND OTHER LIVER DISEASES AND THEIR CLINICAL IMPLICATIONS. (E.) Doniach, D. (Middlesex Hosp. Sch. Med., London), I. M. Roitt, J. G. Walker and S. Sherlock. *Clin. Exp. Immun.* 1(3):237-262, 1966.

high titers of cytoplasmic "M" immunofluorescence occurred in unfixed sections from various organs with the sera of patients with primary biliary cirrhosis. The sera of virtually all these patients contained non-organ specific antibodies which were also found in 31% of patients with cryptogenic cirrhosis and 28% of the active chronic hepatitis cases. In contrast, very low titer were found in only 2 of 28 with extrahepatic biliary obstruction and 1 of 25 with infective hepatitis, and uniformly negative results were obtained in alcoholic cirrhosis, cholestatic drug syndrome and cholestasis associated with ulcerative colitis. These findings illustrate the value this test might have for differential diagnosis between primary biliary cirrhosis and extrahepatic biliary obstruction. Anti-nuclear factors were found in 75% of juvenile cirrhosis, 46% of primary biliary cirrhosis and 38% of the cryptogenic cirrhosis. The incidence of this factor in the other liver groups was higher than the controls. Thyroid specific autoantibodies were increased fourfold in females with active chronic hepatitis but the incidence of thyroid and gastric autoantibodies was not significantly different from the controls in all other liver conditions studied.

- 10 LIVER DISTURBANCES IN ALLERGIC DISEASES OF FURRIERS. (Rus.) Bronshtein, Kh. I. *Gig. Trud. Prof. Zabol.* 10(2):27-33, 1966.

Studies were conducted on 126 furriers (97 females and 29 males; age less than 3-50 yr.) employed in the industry for periods ranging from 6 mo. to 25 yr. who developed Ursol (p-phenylenediamine)-induced allergies. Enlarged liver was found in all patients; respiratory and cutaneous allergic symptoms, along with involvement of digestive tract and neuroendocrinal organs, were also observed. In Ursol allergy, capillary permeability was increased; protein-forming function of liver, puric acid excretion, and blood serum enzyme levels were disturbed; prothrombin index and blood sugar levels were decreased; serum cholesterol deviated from the norm in 12 patients; pigment vol. showed slight changes; biliary tract inflammation was absent. Disturbances of gastric and intestinal secretion and motility were frequent. Bronchial asthma occurred in 51 patients. Following treatment with corticosteroids, ACTH, synthetic antihistaminics, and anticholinergic drugs, the liver decreased in size and its function improved. Blood transfusions were effective in patients with pronounced asthenia. In most of the patients, intradermal and cutaneous allergy tests with extracts from dyed furs and various types of Ursol were positive.

LIVER AND BILIARY TRACT

- 9241 COMPARATIVE IMMUNOLOGICAL STUDIES IN LIVER DISEASES. (E.) Szécsey, G. (Postgrad. Sch. Med., Budapest, Hungary), G. Dóbiás and E. Kerekes. J. Clin. Path. 19(3):275-278, 1966.

Nuclear, mitochondrial, and connective tissue antigens were prepared by fractionation of human liver tissue. To demonstrate the antibodies, parallel antihuman globulin and thrombocyte consumption tests were performed. Positive results occurred with the same frequency with both nuclear and mitochondrial fractions in patients with protracted acute hepatitis, chronic hepatitis, cirrhosis, obstructive jaundice, and cholecystitis; in these cases, serum factors of antibody nature were produced and were demonstrated in those conditions associated with a significant lesion in the parenchyma. The antihuman globulin test yielded positive results more often in cases of liver disease but was less specific than the thrombocyte consumption test. The thrombocyte consumption test also gave positive results in 38 of 159 patients with chronic furunculosis, hydradenitis, rheumatic carditis, and other "mixed" infections. Positive reactions by both tests were about 50% less common during prednisolone therapy (20-30 mg/day) than before or after such treatment. It is advisable to use fractionated antigens for the demonstration of autoantibodies so that undesirable cross reactions may be eliminated.

- 9242 ELECTRON MICROSCOPIC STUDIES OF LIVER TISSUE IN A PATIENT WITH ROTOR'S SYNDROME. (Ger.) Mölbert, E. (U. Freiburg/Breisgau, Germany) and R. Marx. Acta Hepatosplen. (Stuttgart) 13(3):160-175, 1966.

Electron microscopic studies of liver biopsy tissue from a patient with Rotor's syndrome indicated the presence of giant mitochondria with progressive degeneration of the mitochondrial cristae into lamellae lying parallel to the external mitochondrial membrane (similar to the condition seen in obstructive jaundice or virus hepatitis), accompanied by grid-shaped inclusions similar to those resulting from protein deposition or deposition of blocked metabolites. Depositions of pigment in the cytoplasm of epithelial cells was also in evidence, although the source of the pigment could not be demonstrated. Occasional dissociation of epithelial cells accompanied by much increased formation of microvilli throughout the entire cell membrane and occasional, total destruction of an individual cell, was also observed as were fibrin precipitation and much increased formation of fibrous strands within the extracellular spaces. There was no evidence that hepatic conjugation of bilirubin was disturbed.

- 9243 PROCEDURES AND VALUE OF LIVER FUNCTION TESTS WITH BENGAL ROSE AND RADIO-ACTIVE IODINE. (Ger.) Dahl, P. (Med. Acad., Lübeck, Germany) and H. Uthgenannt. Acta Hepatosplen. (Stuttgart) 13(3):137-153, 1966.

Procedures are described in detail for administration and evaluation of a liver function test employing a single injection of bengal rose marked with $0.1 \mu\text{C}$ ^{131}I , with blood taken after 4, 10 and 16 min. Among 39 patients in whom test results were compared with those obtained by the sulfobromophthalein retention test, no significant differences were found. In another comparison, 181 tests were made of patients with fatty degeneration of the liver (29 tests), chronic hepatitis in transition to a cirrhosis (99) or cirrhosis with scarification of the liver (53). The sulfobromophthalein retention test proved more reliable only for the group with chronic hepatitis, while the bengal rose- ^{131}I and the 2-dye excretion tests yielded substantially equivalent results. In 111 clinical tests made on 91 patients with liver and gallbladder disorders, the most severe disturbances of excretion were seen in patients with hepatic cirrhosis or acute hepatitis; only minor disturbances were seen in patients with chronic hepatitis; widely scattered results were obtained among patients with obstructive jaundice or cholestatic hepatosis.

- 9244 IRON ABSORPTION IN IDIOPATHIC HAEMOCHROMATOSIS BEFORE, DURING, AND AFTER VENESECTION THERAPY. (E.) Williams, R. (Southampton Gen. Hosp., England), F. Manenti, H. S. Williams and C. S. Pitcher. Brit. Med. J. 2(5505):78-81, 1966.

Serial measurements of iron absorption in 19 patients with idiopathic hemochromatosis before, during and after venesection therapy indicate that with this condition there is a primary defect in iron absorption which has been depressed by the time

ER AND BILIARY TRACT

presentation because of saturation of iron stores. With these patients, iron absorption values were normal or only marginally increased at the time of presentation, but during venesection therapy the absorption increased progressively, the values ranging from 11-66%. During yr. 1 after termination of therapy, the mean value (6 patients measured) was 65%, an increase which could not be accounted for by persistence of anemia or depletion of iron stores. Plasma iron turnover was increased and surface counting showed diversion of iron to the liver. Skin pigmentation or hepatomegaly did not recur and liver function tests were normal but cirrhosis was histologically still present.

45 EFFECT OF SIDE TO SIDE PORTACAVAL SHUNT ON INTRACTABLE ASCITES, SODIUM EXCRETION, AND ALDOSTERONE METABOLISM IN MAN. (E.) Orloff, M. J. (Harbor Gen. Hosp., Torrance, Cal.). Am. J. Surg. 112(2):287-298, 1966. Report of 9 patients who had advanced cirrhosis and intractable, massive ascites remained free of ascites during follow-up periods of 12-40 mo. following a side-to-side portacaval anastomosis. Only 1 patient failed to survive this shunt procedure. 4 patients had marked salt and water retention and the urinary aldosterone excretion was significantly elevated in the 4 patients who were measured. After the shunt operation, marked diuresis and natruresis occurred, as well as a return of urinary aldosterone excretion to normal levels. The vol. of ascitic fluid removed by operation ranged from 5.8-17.5 liters. Prior to operation, severe hepatic outflow obstruction was seen in all the patients and the resulting elevated portal pressure was reduced to the normal range by the shunt. Liver function has improved somewhat in 7 of the 8 surviving patients, while all have shown a striking improvement in nutrition and vigor.

46 TREATMENT OF HEPATIC COMA BY EXTRACORPOREAL LIVER PERFUSION. (E.) Eiseman, B. (U. Kentucky Sch. Med., Lexington). Ann. Roy. Coll. Surg. Eng. 38(6):329-348, 1966. Extracorporeal heterografts of pig liver have been used in 11 perfusions of 8 preterminal patients in advanced hepatic decompensation, demonstrating the possibility of metabolic and clinical benefit to patients with advanced liver disease. One patient received 3 perfusions over a 12-day period with no evidence of sensitivity reactions. Experiments had previously showed that pig livers, exsanguinated with 8 liters of cold heparinized Ringer's lactate soln., can be perfused with human blood. It was found that all human serum clumped all pig red cells but that human cells are compatible with pig serum. The pig liver will function with any type of human blood, if the pig blood is first washed out. In vitro trials of pig livers, perfused with human blood, were used to study bile production, ammonia clearance, clearance of radioactive rose bengal, galactose conversion, glycogen deposition, protein synthesis from amino acids tagged with C^{14} and a variety of other tests. Technical problems of the human-pig heart perfusion system, such as mechanical and hydraulic factors, vol. flow, oxygenation, temperature regulation and bleeding, have been resolved or are receiving attention.

47 RADIOSILVER IN LIVER SCINTIGRAPHY. (E.) Németh, G. (Municipal Inst. Oncother., Budapest, Hungary), I. Szabó, G. Kárpáti and A. Szekulesz. Oncologia (Basel) 20(1):29-34, 1966. It is proposed in this study to substitute Ag^{111} for Au^{198} in the production of liver scintigrams. The atoxic nature of Ag^{111} in colloidal form and its distribution in the organism were confirmed by animal experimentation. The distribution is similar to that of Au^{198} (90% in Kupffer cells of liver, 10% in reticuloendothelial stem). The advantages claimed for the silver isotope are: it has a longer half-life (7.5 days) as compared to Au^{198} (2.69 days) and silver is more strongly bound to protein, thus being better retained in the liver. It is claimed that the scintigrams obtained with colloidal silver are of better quality and show finer detail. The amount of tracer can be reduced because of more favorable radio-physical characteristics (less gamma emission). The evaluation of the use of radiosilver in scintigraphy is based on experience with 11 patients.

LIVER AND BILIARY TRACT

- 9248 GASTROSTOMY IN CONNECTION WITH SURGERY PERFORMED ON PATIENTS WITH PORTAL HYPERTENSION. (Por.) Couto, D., Jr. (U. Brazil Sch. Med., Rio de Janeiro). Hospital (Rio) 69(4):709-715, 1966.
In 20 patients with portal hypertension, a minimal, decompressive gastrostomy was performed at the time of abdominal surgery, in preference to postoperative nasogastric intubation. Results were considered excellent in 18 of 20, good in 1 of 20 (a patient who experienced 2 mild episodes of vomiting when peristalsis failed to re-establish itself promptly following vagotomy and pyloroplasty) and poor in 1 of 20 (a patient in the first trimester of pregnancy who had already developed morning sickness).

Hepatic Injury

- 48 HEPATIC AND RENAL CHANGES INDUCED BY SYNTHETIC PROGESTOGENS AND NATURAL PROGESTERONES. (E.) Tóth, F. (U. Budapest Sch. Med., Hungary). Acta Morph. Acad. Sci. Hung. 14(1):1-6, 1966.
- When progesterone, both natural and synthetic, was admin. to female rats in doses equivalent to those given therapeutically for threatened abortion, no changes were seen in the liver or kidney of these rats. However, the alkaline and acid phosphatase reactions became more pronounced in both the kidney and the liver. Larger doses of progesterone induced grave fatty degeneration in the liver and kidney of both pregnant and nonpregnant rats, whereas, intermediate doses affected only the pregnant animals. The hepatic lesion was diffuse, mostly centrilobular and the kidney lesion was mostly in Henle's loops. The major part of the lipoids from this fatty degeneration were steroid hormones. These degenerative lesions disappeared 7 days after the termination of progesterone.
- 349 PERMEATION OF TOXINS INTO THE LIVER. CHARACTERISTICS OF THE CELL MEMBRANE. (Ger.) Kurz, H. (U. Munich, Germany). Naunyn Schmiedeberg. Arch. Exp. Path. 254(1):33-44, 1966.
- In vitro* studies of intact mouse livers incubated with a number of hepatotoxic substances confirmed that the rate of hepatic permeability was directly dependent on the coefficient of diffusion of the test substance, appearing to confirm the involvement of a lipid membrane. Failure to demonstrate such dependency when sections or small pieces of rabbit or mouse liver were incubated with the toxins was attributed to damage of the tissue structure during the cutting process (e.g., tearing or penetration of cell walls). Tested substances included amidopyrine, thiopental, pentobarbital, phenazone, barbital, diethylamine, salicylic acid, sulfaguanidine, nitrosalicylic acid, nitrofurantoin, triacetic acid and sulfosalicylic acid. A comparison of the rates of permeability seen under conditions of perfusion, incubation and incubation following removal of substantial portions of the serous membrane led to the conclusion that a type of membrane must be involved which showed a combination of lipid and permeable membrane characteristics. It was further concluded that the membrane in question must be the wall of the hepatic cell itself.
- 350 THE RELATIONSHIP BETWEEN CHEMICAL STRUCTURE AND PROTECTIVE EFFECT OF DITHIOCARBAMATE DERIVATIVES AGAINST EXPERIMENTAL HEPATIC INJURY INDUCED BY CARBON TETRACHLORIDE ADMINISTRATION IN RATS. (E.) Sakaguchi, T. (Dainippon Pharm. Co., Ltd., Osaka, Japan), H. Nishimura, K. Masuda, I. Tsuge, K. Onishi and H. Tatsumi. Biochem. Pharmacol. 15(6):756-758, 1966.
- Male Donyru rats weighing 180-200 g had compounds to be tested for protective effect admin. orally just prior to i.p. inj. of CCl_4 (intragacanth suspension, 0.1 ml/kg). Blood collected from the heart under anesthesia was centrifuged and the plasma tested for glutamic-oxalacetic and glutamic-pyruvic transaminases. Reduction of plasma transaminase corresponded to the degree of protection. Compounds having a CSSH radical on an N or O atom exhibited strong protective action against CCl_4 , whereas their ester and ring forms showed no protective effects; no protection was afforded by thio compounds. Tetraethylthiuram disulfide and CS_2 may exert their protective action by being converted to dithiocarbamate in the animal body.
- 351 ALTERATIONS IN ENZYME ACTIVITY OF THE LIVER LOBULE DURING CHRONIC ETHIONINE INJURY. (E.) Morrison, G. R. (Washington U. Sch. Med., St. Louis, Mo.), C.-H. Cheng, I. E. Karl and R. E. Shank. Cancer Res. 26(4):715-720, 1966.
- Normal female Sprague-Dawley rats (175-250 g) were placed in 3 groups of 6 each and fed a prescribed diet. Group 1 only received 0.5% ethionine added to the diet; Group 2 was pair-fed with Group 1; Group 3 was fed freely. Each wk. 1 ethionine rat, its pair-fed control, and 1 free-fed control were killed. The liver was rapidly excised, biopsied for frozen-dried sections and homogenates. Only the tissues adjacent to the capsule between the portal tract and central vein were used. After dehydration and weighing these sections were placed in microtest tubes for enzyme assays. For each liver triplicate determinations were made of protein and DNAP in

LIVER AND BILIARY TRACT

Hepatic Injury

both homogenates and frozen sections. The liver responds to ethionine injury by hyperplasia. The new cells formed in the periportal and central areas of the lobules contained less protein and had lower activities for most of the enzymes studied than did normal parenchymal cells in corresponding areas of livers of pair-fed rats. However, on a dry wt. basis, protein content and enzyme activity of the injured lobules exceeded control values. These excessive protein responses are correlated in time with the hyperplasia induced by ethionine. There is some evidence that ethionine may be incorporated in proteins.

- 9352 POLYRIBOSOMES IN RAT TISSUES. III. THE RESPONSE OF THE POLYRIBOSOME PATTERN OF RAT LIVER TO PHYSIOLOGIC STRESS. (E.) Webb, T. E. (U. Wisconsin, Madison), G. Blobel and V. R. Potter. *Cancer Res.* 26(2)(Pt. 253-257, 1966.

Liver tissue was obtained from 250 g male rats fasted and/or inj. i.p. with 0.5 mg glucagon to reduce glycogen below levels which interfere with the isolation of polyribosomes. The total ribosome pattern was obtained by layering the postmitochondrial supernatant (S₂) after treatment with deoxycholate (I) directly over the sucrose gradient. The C-ribosomes were purified from the I-treated S₂ by centrifuging through a discontinuous gradient of 0.5-2.0 M sucrose. The C-ribosomes represent the size distribution of mainly the polyribosomes and monomers plus polyribosomes. The size distribution of polyribosomes is modified by prolonged fasting, partial hepatectomy, and the admin. of dinitrophenol or CCl₄. CCl₄ also caused release of ribosomes bound to the endoplasmic reticulum, in addition to extensive breakdown of the polyribosomes. The results suggest that the size distribution is not simply a function of the relative conc. of the ribosomes and messenger ribonucleic acid (mRNA) but rather depends on the energy supply and the relative sizes of the mRNA that is being produced. In general, the number of ribosomes sedimenting in the heavy polyribosome region appears to correlate with the predicted growth rate (protein synthesizing capacity) of the tissue.

- 9353 STUDIES ON THE EFFECT OF LIVER FUNCTION ON THE METABOLISM OF ORGANIC MERCURY COMPOUNDS. (Jap.) Norimune, S. (Tokushima U. Sch. Med., Japan). *Shikoku Igaku Zasshi (Shikoku Acta Med.)* 22(1):136-149, 1966.

The effect of the state of liver function on urinary and fecal excretion and hepatic and renal accumulation of organic mercury compounds was studied in rabbits and rats. In rabbits treated for relatively long periods (150 days), phenylmercuric acetate (I) was rapidly excreted in a manner similar to HgCl₂; ethylmercuric chloride (II) was excreted slowly and mostly into the feces, its renal excretion showing repeated fluctuations. In rabbits treated with I, urine and fecal excretion of Hg was markedly disturbed when liver function was damaged by prior admin. of CCl₄ and did not increase upon recovery from liver damage. When rats were intoxicated with CCl₄, or treated with methionine and vitamin B₁₂ prior to the admin. of I, marked increase in the hepatic content of Hg was observed after 48 hr. in the former group, causing corresponding decrease in the fecal excretion of the mercuric compound; no significant differences in the renal accumulation of Hg were noted. When II replaced I, hepatic and renal accumulation decreased and appeared to be distributed in other parts of the body. The importance of the state of liver function and variability in the mode of excretion of different Hg compounds are stressed in relation to the diagnosis, treatment, and management of patients with or subject to intoxication from organic mercury compounds.

- 9354 DENERVATION OF THE HEPATIC ARTERY AND ITS EFFECT ON THE PROGRESS OF EXPERIMENTALLY-INDUCED HEPATITIS. (Fr.) Nana, A. (First Surg. Clin., Cluj, Rumania), C. Mircioiu, E. Neumann, Z. Uray, C. Stroila and D. Suteu. *Lyon Chir.* 62(2):217-228, 1966.

Prior denervation of a 1-cm segment of the hepatic artery in rats and rabbits (by painting the surrounding tissues with phenol) and of a 1.5-2.0-cm segment in dogs (by surgery) increased the regeneration rate of hepatic lesions induced by i.p. inj. of CCl₄. This was accompanied by significant degrees of inhibition of the toxin-induced decrease of glycogen content and ornithylcarbonyl transaminase activity; moderate inhibition of the decrease of intrahepatic oxygen consumption and

iliary elimination of conjugated bilirubin; a moderate increase of the coefficient of oxidative phosphorylation, as compared to a very marked decrease in toxin-treated controls. Intracellular penetration of tetrabromotetraiodofluorescein (rose bengal) was increased and intracellular albumin content was decreased, suggesting increased resistance to toxic activity. It is concluded that denervation of the hepatic artery may be of value in the treatment of intrahepatic cholestasis in the absence of severe or extensive hepatic lesions.

- 355 THE ROLE OF THE RETICULOENDOTHELIAL SYSTEM IN THE STEATOGENIC EFFECTS OF ETHYL AND ISOPROPYL ALCOHOL IN RATS. (Fr.) Gaillard, D. (Inst. Physiol., Fac. Sci., Toulouse, France), S. Mitjavila and R. Derache. C. R. Acad. Sci. (Paris) 262(20)(Ser. D):2169-2171, 1966.

In rats, admin. of water by gavage was followed by a relatively slight, but significant increase of hepatic triglycerides. Similar admin. of 100-proof ethyl or isopropyl alcohol was followed by a very marked increase of triglycerides infiltrating the liver, an effect which was not produced by other alcohols and which was inhibited by i.v. inj. of ethyl stearate 72 hr. previously. Although ethyl stearate itself exerted no effect on hepatic triglyceride content, it reduced the percentage increase induced by ethyl alcohol to the same level as that induced by water and inhibited the increase which followed isopropyl alcohol virtually totally. It is concluded that blockage of the reticuloendothelial system prevented mobilization of the lipids in fatty tissues, since serum triglyceride levels were not affected at any time during the study.

- 356 SPONTANEOUS AND DIET-INDUCED HEPATIC FIBROSIS IN MICE OF THE C STRAIN. (E.) Clower, B. R. (U. Mississippi Sch. Med., Jackson) and W. L. Williams. Am. J. Anat. 118(2):391-409, 1966.

Spontaneous fibrosis developed with aging in 60% of 146 highly inbred C-strain mice at the end of 66 wk. This fibrosis was usually subcapsular, but occasionally it was perivenous or intralobular. Reticular fibers were the chief component and the livers were not fatty. When these mice at the age of 3-4 mo. were placed on a diet high in fat (40% lard), low in protein (8% casein) and deficient in lipotropic substances, the fibrosis accelerated and was accompanied by liposis. In this dietary group (45 mice), the fibrosis showed 3 distinct patterns: most common was subcapsular fibrosis which developed within a month; less frequent in occurrence was fibrous septa which extended chiefly from central veins and produced pseudo-lobulation or pseudoencapsulation of areas of parenchyma; and, least commonly, was intralobular fibrosis unrelated to the capsule or to veins. Collagen was present in subcapsular and perivenous fibrosis by wk. 16 and in the intralobular type by wk. 52. All types consisted initially of reticular fibers. Massive atrial thrombosis occurred in only 5 mice from the experimental groups which is a far lower rate than seen in other mice strains on such a diet.

- 357 EFFECT OF ETHANOL ON RAT LIVER. I. ENZYMIC AND HISTOLOGICAL STUDIES OF LIVER MITOCHONDRIA. (E.) Kiessling, K.-H. (U. Uppsala, Sweden) and L. Pilström. Quart. J. Stud. Alcohol 27(2):189-200, 1966.

For 5 mo. 15% and 25% ethanol soln. were given alternately, 7 and 14 days, resp., as the only drinking fluid to Wistar albino rats and liver biopsies were taken every 30 days. After 90 days, the size of the liver mitochondria (observed with an electron microscope) in the alcohol-treated rats was significantly greater than those of the controls which had drunk an isocaloric sucrose soln. Within the experimental group no statistical difference was found when the following samples were compared for size: 90 and 120 days, 120 and 150 days or 90 and 150 days. The oxidation of pyruvate, succinate, glutamate and β -hydroxybutyrate was significantly slower in liver mitochondria from the treated rats, whereas no change was seen when α -glycerophosphate was the substrate. With these substrates, oxidative phosphorylation was unchanged except with β -hydroxybutyrate where the rate was 60% of that of the control. The activity of phosphofructokinase in liver from males and lactate dehydrogenase in liver from females increased as a consequence of the alcohol treatment, whereas the activity of aldolase, glycerophosphate dehydrogenase, malate dehydrogenase and isocitrate dehydrogenase showed no changes.

- 9358 LIGHT AND ELECTRON MICROSCOPY OF DICHLORODIPHENYLTRICHLOROETHANE (DDT) POISONING IN THE RAT LIVER. (E.) Ortega, P. (Mt. Zion Hosp., San Francisco, Cal.). Lab. Invest. 15(4):657-679, 1966.

Light and electron microscope studies were performed on the livers of 38 male Sherman albino rats fed standard diets containing dichlorodiphenyltrichloroethane (DDT; 100-2,500 ppm) for 1-6 mo. and sacrificed at regular intervals. Characteristic histologic lesions consisted of hepatocellular enlargement, central cytoplasmic hyalinization, peripheral migration of ergastoplasm, and cytoplasmic inclusion body formation in hepatocytes. Studies revealed that hyalinization was due to marked proliferation of the agranular endoplasmic reticulum. Inclusion bodies appeared to represent specialization of this system and to possess a complex fine structure. Their capsules had a myelin-like configuration with concentric arrays of membranes; the interior contained vesicular profiles and a variety of cytoplasmic organelles, especially rich in lipid. The granular lamellar arrays of ribosomes were displaced peripherally and corresponded to ergastoplasmic margination. Other liver cell constituents showed minor alterations. Of unusual interest is the fact that the striking cytoplasmic changes are apparently compatible with protein synthesis, glycogen storage, normal wt. gain, and infrequent toxic signs. The possible function of agranular membranes in the detoxification of various chemicals is discussed.

- 9359 EFFECTS OF ADENYLIC COMPOUNDS ON HEPATIC STEATOSIS IN THE RAT. (Fr.) Garigue, J. (U. Toulouse Sch. Med., France), J.-C. Dumas, P. Gayrel and G. Roux. C. R. Soc. Biol. (Paris) 159(12):2530-2532, 1965.

In vivo studies of the effects of 3 adenylic compounds on nutritionally-induced fatty degeneration of the liver, in rats, showed that simultaneous i.m. admin. of adenine or of adenosine afforded a degree of protection against protein-deficient, high-fat diet which was essentially equal to that provided by p.o. admin. of choline chloride. A somewhat less marked, but significant, degree of protection was afforded by 2-thioadenine, i.m., while p.o. admin. of adenosine (at least at the dosage level employed) was considerably less satisfactory.

- 9360 INFLUENCE OF CHLORPROPAMIDE ON CERTAIN BIOCHEMICAL INDICES OF THE LIVER UNDER NORMAL CONDITIONS AND IN EXPERIMENTAL TOXIC HEPATITIS. (Rus.) Leites, S. M. (Cent. Inst. Postgrad. Med. Train., Moscow) and N. K. Abdullaev. Biull. Eksp. Biol. Med. 61(3):55-59, 1966.

Intact albino rats (wt. 180-200 g) showed characteristic increases in liver glycogen and protein nitrogen content following the admin. of chlorpropamide (5 mg/100 g/day p.o. for 50 days); lipid content increased somewhat 30-40 days after the start of treatment but was unchanged later; β -lipoprotein content decreased during the first 30 days; wt. gain was twice that of controls after 50 days. In a second experiment, chronic toxic hepatitis was induced in rats by CCl_4 (0.12 ml/100 g s.c. twice weekly for 65 days); 1 group was treated with chlorpropamide (as above) from day 15 of poisoning on, and the others served as controls. Studies were performed every 10 days from day 25-65 and showed increased hepatic glycogen and protein nitrogen levels and decreased total lipid content. Opposite effects were seen in controls. The coefficient of proteolysis (relation between residual nitrogen and total nitrogen) was decreased and total serum protein levels were increased in treated rats. Wt. gain was almost 3 times more than that of controls. Thus, chlorpropamide-induced insulin secretion in rats with chronic toxic hepatitis corrects the basic hepatic metabolic pathology, restores glycogen levels, inhibits development of fatty infiltration, and normalizes serum protein and β -lipoprotein levels.

- 9361 A STUDY OF THE EFFECTS OF GLUCURONIC ACID IN EXPERIMENTALLY-INDUCED HEPATIC INTOXICATION. (Sp.) Daufi Moreso, L. Med. Clin. (Barc.) 46(2):123-130, 1966.

Daily admin. of various doses of glucuronolactone in aqueous soln., over various periods of time up to 1 mo. previously, following, or simultaneously with various (single) toxic doses of CCl_4 had no significant effect on the hepatic lesions induced by the latter in mice. The related literature is reviewed in some detail.

- 362 PEROXIDATION OF LIVER LIPIDS IN THE PATHOGENESIS OF THE ETHANOL-INDUCED FATTY LIVER. (E.) Kalish, G. H. (U. Tennessee Med. Units, Memphis) and N. R. Di Luzio. Science 152(3727):1390-1392, 1966.
- Admin. of coenzyme Q₄ (50 mg/100 g) to rats that had previously received a single, toxicating dose of ethanol significantly inhibited the ethanol-induced increase in the liver triglyceride conc. and completely prevented the previously observed increment in lipid peroxides. This inhibitory process was specific as the adipose peroxide conc. was not altered by coenzyme Q₄. After the ethanol, there was a significant increase in the liver wt. along with the increased liver triglyceride and increased peroxidation of lipids.
- 363 ACUTE LIVER INJURY DUE TO ALBITOCIN. (E.) Kerr, J. F. R. (U. Queensland, Brisbane, Australia) and A. W. Pound. Aust. J. Exp. Biol. Med. Sci. 44(2):197-204, 1966.
- Albitocin, a triterpenoid glycoside extracted from the bark of Albizia gummifera which is known for its powerful oxytocic activity, proved to be a potent hepatotoxin for both mice and rats. Generally, the severity of the liver lesion correlated with the gravity of the illness produced. Liver damage progressed as follows: enlargement of parenchymal cell nuclei and peripheral zonal fatty infiltration, followed by coagulative necrosis in the intermediate liver zones and, finally, irreversible liver cell damage in the outer two-thirds of the lobules. In this last stage, the cytoplasm was swollen with spherical bodies which were rich in acid phosphatase and esterase and were similar to large lysosomes described in other types of liver injury. The nuclei of these cells were vacuolated or pyknotic. When albitocin was admin. by stomach tube rather than i.p. inj., it was less toxic. Enrichment of the diet with α -tocopherol or admin. of promethazine did not protect against the albitocin.
- 364 PROTEIN AND ENZYME CONTENT OF SUBCELLULAR STRUCTURES IN EXPERIMENTAL ALCOHOLIC AND ALIMENTARY LESIONS OF THE LIVER. (Rus.) Mansurov, K. K. (Tadzhik Inst. Region. Med., Dushanbe, USSR), L. A. Lopatina, R. P. Molchagina, I. V. Borisenko and G. P. Sokol. Vop. Pitan. 25(1):33-39, 1966.
- Protein content and enzyme activity were investigated in hepatic subcellular structures of 21 rabbits treated by long-term admin. of alcohol (50%; 2 ml/kg) and fed either (Group 1) or nutritionally deficient (Group 2) diets. At the end of 1 yr., aldolase activity in Group 2 was absent in nuclear, mitochondrial, and microsomal fractions and decreased 2-fold in the cytoplasm; in Group 1, aldolase activity was markedly decreased in the nucleus, microsomes and cytoplasm. Alkaline phosphatase and ATPase levels were decreased in both groups. Total protein content of the cytoplasm and mitochondria was decreased in Group 1 and increased in Group 2, while that of the microsomal fraction was increased in Group 1 and decreased in Group 2. Similar studies were conducted in 9 rabbits fed a substandard diet containing 40% glucose (Group 3) and 120 rats fed choline-deficient diets containing 4% protein (Group 4). In Group 3, aldolase activity of the cytoplasm, nucleus, and mitochondria was decreased along with total protein content of the cytoplasm; serum glutamic-pyruvic and oxalacetic-transaminase levels in liver homogenates and single fractions showed a max. decrease by day 150 and 210, resp. In Group 4, transaminase activity was decreased in the mitochondria and variable in the cytoplasm; serum glutamic-oxalacetic transaminase levels remained high for long periods, while the decrease in serum glutamic-pyruvic transaminase activity was parallel in homogenates, mitochondria, and cytoplasm. By day 90, alkaline phosphatase activity increased and total protein content decreased in animals with hepatic fibrosis. Total protein content of the mitochondria decreased by day 30 and remained low during the rest of the experiment; protein content was decreased to a lesser degree in the cytoplasm and was unchanged in the nucleus and microsome.
- 365 ORNITHINE-TRANSCARBAMOYLASE (CITRULLINE SYNTHETASE) IN SERUM AFTER LIVER INJURIES. (Cz.) Kulhanek, V. and J. Kroupa. Cas. Lek. Cesk. 105(13):345-350, 1966.
- The activity of citrulline synthetase (I) was determined in 386 patients with

infectious or non-infectious diseases or after surgery, and in 225 patients after injury. Animal studies included 24 guinea pigs and 36 rabbits with experimental traumatic injuries. Severe hepatic damage at animal autopsy correlated with marked increases in I activity. In the clinical study, the I values increased slightly as a manifestation of the general response to injury (not evident in mild injury cases). In patients with hepatic injury, the serum I increased markedly almost immediately after injury, reached a max. in 24 hr., and returned to normal on about day 5. It is suggested that I values may aid in clinical diagnosis of liver injuries.

- 9366 EARLY HEPATIC PARENCHYMAL CHANGES INDUCED IN THE RAT BY AFLATOXIN B₁. (E.) Butler, W. H. (U. London Coll. Med. Hosp.). Am. J. Path. 49(1):113-128, 1966.

Unanesthetized male Wistar rats (150 g) were given single doses by stomach tube of 1 mg crystalline aflatoxin B₁ dissolved in dimethylformamide. Control rats received a similar dose of the solvent alone. Animals were sacrificed 1, 3, and 6 hr. after treatment, and hepatic tissue from the median lobe was examined microscopically. Sequential ultrastructural changes were observed in liver parenchymal cells. At 1 hr., some dilatation of endoplasmic reticulum cisternae and dislocation of ribosomes occurred in periportal cells. At 3 hr., disruption of endoplasmic reticulum was more evident; centrilobular cells remained normal. At 6 hr., periportal cells showed further disruption with mitochondrial alterations. Centrilobular parenchymal cells showed dilatation of endoplasmic reticulum cisternae and dislocation of ribosomes. At 3 and 6 hr., formation of nucleolar caps was seen. There seems to be a correlation between inhibition of protein synthesis and disruption of endoplasmic reticulum.

- 9367 THE METABOLISM OF RADIOACTIVE ZINC IN THE LIVER OF RATS DAMAGED BY A SINGLE ADMINISTRATION OF CARBON TETRACHLORIDE. I. RADIOISOTOPE STUDIES. (E.) Wysocki, K. (Acad. Med., Poznan, Poland), L. Owczarek, W. Fenrych, S. Gorski and C. Majewski. Acta Med. Pol. 7(1):97-102, 1966.

The uptake of Zn⁶⁵ following s.c. inj. of 12.8 µc of Zn⁶⁵Cl₂ (specific activity 28 mc/g Zn) was studied in the livers of Wistar rats (wt. 200-230 g) damaged by a single s.c. inj. of 0.5 ml of CCl₄. Results indicated that the % of Zn⁶⁵ uptake was lower in the CCl₄-treated group than in controls (NaCl-treated) after 16 hr.; the difference between the 2 groups decreased after 24 and 36 hr. but increased after 48 hr., at which time radioactivity in damaged livers was greater than that of controls. Reduced levels after 48 hr. in healthy animals indicate impaired biliary elimination of the isotope. It is concluded that the observed differences in radioactivity of the blood between the experimental and control groups of rats are related to the lesions in the liver parenchyma.

- 9368 BEHAVIOR OF SERUM GLYCOPROTEIN AND HAPTOGLOBIN LEVELS IN EXPERIMENTAL LIVER DAMAGE IN RATS. (E.) Piukovich, I. (U. Szeged Sch. Med., Hungary), L. Varga, M. Gábor, M. Tényi, E. Horváth and A. Simon. Med. Pharmacol. Exp. (Basel) 14(5):485-492, 1966.

Thirty hr. following an explorative laparotomy in rats the following results were obtained: the value of the diphenylamine reaction reached a max. which was significantly greater than in the controls; the serum glycoprotein level increased to its max.; the serum neuraminic acid level showed a considerable elevation; and the serum haptoglobin level had increased to double the normal value. Thirty hr. following the s.c. admin. of 0.2 ml of CCl₄ all these serum levels were also elevated, but the increase was not as great. Except for the neuraminic acid conc., these levels also increased following a partial hepatectomy (70% removal), but they were always less than that following the explorative laparotomy and they did not usually occur until 120 hr. later. The rise in the glycoprotein conc. (in the rat) appears to depend on the extent of liver injury.

- 9369 TETRACYCLINE TOXICITY. A CLINICOPATHOLOGIC STUDY WITH SPECIAL REFERENCE TO LIVER DAMAGE AND ITS RELATIONSHIP TO PREGNANCY. (E.) Davis, J. S.

(Baylor U. Coll. Med., Houston, Texas) and R. H. Kaufman. Am. J. Obstet. Gynec. 95(4):523-529, 1966.

x patients, 4 of them pregnant women, developed jaundice and azotemia (and eventually died) during the course of antibiotic therapy which included daily i.v. doses of tetracycline (0.5-4 g; 1-9 days) for acute infections. Jaundice was noted initially in all the women and at necropsy in all 6 patients. Major anatomical changes seen included a large fatty liver in which the fat droplets were finely dispersed in the cells and throughout the lobule, fatty degeneration of the renal tubular epithelial cells, serous effusions, hemorrhages and focal fat necrosis in the pancreas and widespread petechiae and ecchymoses. The metabolic disorders were probably brought about by the ability of the tetracyclines to chelate certain metal ions, plus the fact that liver conc. are usually higher than that of the blood. Initially, the women manifested nausea and vomiting, lethargy and coma, hypotension, mild abdominal pain, acidoses, elevated leukocytes, serum glutamic-oxaloacetic and glutamic-pyruvic transaminase, low serum calcium and moderate to marked elevation of serum amylase levels.

70 EXPERIMENTAL TOXIC CIRRHOSIS IN THE RAT. KINETICS OF HEPATOCYTE PROLIFERATION DURING INTERMITTENT CARBON TETRACHLORIDE INTOXICATION. (E.) Shea, S. M. (Harvard Med. Sch., Boston, Mass.). Exp. Molec. Path. 5(3):311-328, 1966.

rrhosis was induced in male albino rats by repeated i.p. inj. of 0.03 ml/100 g body wt. of CCl_4 in order to obtain data concerning hepatocyte renewal which would allow evaluation of the parameters of a stochastic model of this renewal. One hr. before sacrifice, 2 $\mu\text{C/g}$ of H^3 -thymidine was admin. i.v. to the rats. The order of magnitude of the cell populations involved was evaluated in relation to histologic determination of the hepatocyte populations of resulting cirrhotic pseudobulbs. Birth-rate data were obtained from determinations of the mean fraction of hepatocyte labeling with H^3 -thymidine, and of the standard deviation of the labeling fraction. As the labeling was quite variable, a birth-rate function and death-rate function were constructed showing random fluctuation of appropriate magnitude about the mean. These functions, with the initial size of the population, constituted the stochastic model. Study of this model by a Monte Carlo computer simulation showed that this system will undergo considerable random fluctuations in population size.

871 OBSERVATIONS ON THE SUBCELLULAR ORGANIZATION OF HEPATIC PARENCHYMAL CELLS. II. EVOLUTION OF REVERSIBLE ALTERATIONS INDUCED BY HYPOXIA. (E.) Glinsmann, W. H. (Walter Reed Army Res. Inst., Washington, D. C.) and J. L. E. Ericsson. Lab. Invest. 15(4):762-777, 1966.

hepatic parenchyma cell alterations were studied by electron microscopy in maleistar rats subjected to hypoxia (5 or 7.5% oxygen in nitrogen) for 2-4 hr. Mortality was higher (LD_{50} at 2 hr.) in the 5% oxygen group than in the 7.5% group (LD_{50} at 4 hr.). After 2 hr. of hypoxia, increased numbers of large, early cytosegresomes ("autophagic vacuoles") containing well identifiable cytoplasmic organelles were observed. Later, the segregated organelles showed gradual transformation to dense, membranous, and granular structures similar to those seen in the cytosegresomes of normal cells. The cytosegresome walls seemed to be formed by wrapping of cisternae of the endoplasmic reticulum around damaged portions of the cytoplasm. The single limiting membrane surrounding most cytosegresomes was probably created through a gradual process of narrowing or "compaction" of the walls of endoplasmic cisternae which ultimately fused. During the period of increased cytosegresome formation, decreased budding activity of Golgi cisternae to form Golgi vacuoles and presumably "primary" cytosomes were noted. This suggested a reversibly disturbed balance between primary and secondary cytosomes. Immediately following the hypoxia period, universal swelling of mitochondria was observed but seemed to be rapidly reversible. The cytoplasm was essentially normal 24 hr. after injury. Results indicate a rapid turnover of cytosegresome-derived cytosomes, some of which appeared to be extruded into bile capillaries.

- 9372 EFFECTS OF CIRRHOSIS AND OTHER LIVER INSULTS ON INDUCTION OF LIVER TUMORS BY AFLATOXIN IN RATS. (E.) Newberne, P. M. (Massachusetts Inst. Techn. Cambridge), D. H. Harrington and G. N. Wogan. Lab. Invest. 15(6):962-966, 1966.

When male rats (CD) were fed a cirrhotogenic diet until cirrhosis was induced and were then given an adequate diet prior to receiving aflatoxin-contaminated peanut meal, the carcinogenic effect of the aflatoxin seemed to be potentiated by the cirrhosis. A lesser potentiation is also suggested if the aflatoxin is admin. as soon as the cirrhosis is induced. Choline deficiency, partial hepatectomy, repeated biopsy and iron inj., alone or in combination, did not result in liver tumor induction unless aflatoxin was superimposed at some point during the experiment. Cirrhosis was the only form of liver insult which seemed to actually influence the neoplasia. Aflatoxin and ethionine appeared to have a syncarcinogenic effect.

- 9373 LIPOPEROXIDATION OF RAT LIVER MICROSOMAL LIPIDS INDUCED BY CARBON TETRACHLORIDE. (E.) Recknagel, R. O. (Western Reserve U., Cleveland, Ohio) and A. K. Ghoshal. Nature (London) 210(5041):1162-1163, 1966.

A method of study of lipoperoxidation of rat liver microsomal lipids induced by carbon tetrachloride is presented. Lipids extracted from peroxidized rat liver microsomes exhibit typical diene conjugation absorption spectra implying that destructive lipoperoxidation has occurred. This work supports the hypothesis that CCl₄ is split homolytically in or near the lipoidal components of the endoplasmic reticulum of the hepatic parenchymal cells. A possible mechanism involving the free radical formed above and leading to the pathologic results of CCl₄ poisoning is presented.

- 9374 EFFECT OF INTRAABDOMINAL INJECTIONS OF 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE ON ADENYLIC ACID DEAMINASE ACTIVITY AND NUCLEAR RIBONUCLEIC ACID METABOLISM OF RAT LIVER. (E.) Kizer, D. E. Viral Hepatitis

- 6 STUDY OF SERUM LACTIC AND PYRUVIC ACIDS DURING PHYSICAL EFFORT IN PATIENTS WITH CHRONIC HEPATITIS FOLLOWING INFECTIOUS HEPATITIS. (Rum.) Pappo, A. (Inst. Intern. Med., Bucharest, Rumania), I. Apostolescu, M. Georgescu, R. Cretescu, M. Zamfirescu-Gheorghiu and V. Runcan. Stud. Cercet. Med. Intern. 7(2):135-142, 1966.
- Group of 53 patients with chronic hepatitis following infectious hepatitis (43) compensated cirrhosis of diverse etiology (10) were subjected to a strenuous effort and to a mild effort, 31 patients and 12 normals; and 22 patients and 6 normals, resp., following which lactic and citric acid were studied in the first group and lactic and pyruvic acid in the second group (blood levels in mg%). A significant increase of lactic acid values after effort and decrease after a 60-min. rest period were found in both patients and controls. Highest elevations (115 mg%) were found in patients showing a severe, evolutive chronic hepatitis. At the end of a 60-min. rest period blood lactic acid levels fell below the initial levels, this fall being more pronounced in the normals. Lactic acid changed more markedly as a function of the effort performed when the chronic hepatitis resulted from infectious hepatitis, than when it had a different etiology. Citric acid values at the end of the effort were less elevated in patients than in the controls. Original pyruvic acid values were greater in patients than in normals.
- 7 THE CLINICAL USE OF DRIED FIBRINOGEN (HUMAN) AND THE RISK OF TRANSMITTING HEPATITIS BY ITS ADMINISTRATION. (E.) Anderson, H. D. (Michigan Dept. Health Lab., Lansing), K. B. McCall, J. T. Sgouris and S. T. Gibson. Transfusion 6(3):234-246, 1966.
- 6-mo. follow-up period showed that hepatitis occurred at the rate of 8.6% in patients who had received a total of 1,001 U of dried human fibrinogen plus 59 pints of whole blood. The small group of 58 patients who received fibrinogen alone showed a rate of 1.7% (one case of hepatitis). The fibrinogen was prepared from large pools of plasma by the McCall method, irradiated with UV light, and distributed nationwide. The results obtained with its usage showed it to be safe, effective and a decisive factor in some cases. A strikingly long incubation period of at least 80 days for the hepatitis suggested an effect of pooled gamma globulin on the hepatitis virus sufficient to modify its ability to infect man. The use of large plasma pools did not appear to increase the risk of hepatitis over that found with use of very small pools.
- 8 ADSORPTION OF RHESUS ERYTHROCYTES TO LIVER TISSUE FROM PATIENTS WITH HEPATITIS. (E.) O'Connell, C. J. (New York State U. Sch. Med., Buffalo) and J. P. Nolan. J. Lab. Clin. Med. 67(6):994-999, 1966.
- The adsorption of rhesus RBC was studied in liver tissue specimens obtained by needle biopsy or at autopsy from 100 patients with various liver diseases. Seven patients had acute infectious hepatitis; the other 93 had a variety of normal and diseased states including cirrhosis, fatty degeneration, carcinoma, and various hepatic inflammatory states. All 7 specimens from patients with viral hepatitis had strongly positive hemadsorption tests even when tested with RBC derived from different monkeys and after several wk. of storage at 4°C. Approx. 33% of specimens from the other subjects had positive tests resembling those seen in hepatitis. However, the frequency of positive specimens in hepatitis could be shown to differ from that in other conditions with a high order of significance. Further investigation showed that in hepatitis liver the factor causing rhesus hemadsorption is resistant to heat up to 56°C. In 1 instance, the factor was inhibited with the use of serum from a patient in convalescence from viral hepatitis.
- 9 PLASMA INSULIN ACTIVITY IN PATIENTS WITH ACUTE EPIDEMIC HEPATITIS. (Rus.) Leibush, B. N. (Leningrad Sanit.-Hyg. Med. Inst., USSR). Klin. Med. (Moskva) 43(11):58-63, 1965.
- Plasma insulin activity was studied by the isolated rat diaphragm method in patients with acute infectious hepatitis of varying severity and in 14 apparently

healthy subjects (age 17-42 yr.). Insulin activity ranged from 8-22 $\mu\text{g/ml}$ (median 0-15 $\pm 1.4 \mu\text{g/ml}$) in healthy fasted subjects and from 15-70 $\mu\text{g/ml}$ (median 26 $\pm 3 \mu\text{g/ml}$) in hepatitis patients at the peak of jaundice. Increased insulin activity was more pronounced in the mild forms of the disease, less pronounced in moderate forms, and absent in severe forms. During clinical recovery, values were higher (19-63 $\mu\text{g/ml}$; median 38 $\pm 3.9 \mu\text{g/ml}$) than those obtained in early tests. After glucose loading, median values of insulin activity were 23 $\pm 1.8 \mu\text{g/ml}$ in hepatitis patients at the peak of jaundice, 45 $\pm 5.1 \mu\text{g/ml}$ during convalescence, and 31 $\pm 1. \mu\text{g/ml}$ in healthy subjects. A parallelism was noted between insulin activity change and the extent of hepatic reparative processes, indicating an interdependence of the 2 phenomena.

- 9410 STUDIES ON THE ACTION OF CORTISONE IN PHYSIOPATHOLOGIC SYNDROMES OF CHRONIC HEPATITIS. (Rum.) Fodor, O. (Inst. Med. Physiol., Cluj, Rumania), F. Barbarino, A. Nicoara and I. Fatila. Med. Intern. (Bucur.) 18(2):203-217, 1966.

Clinical studies in 30 patients with chronic postviral hepatitis revealed several humoral and biochemical changes after treatment with dexamethasone (5 mg/day) for 5 days. Serum glutamic pyruvic and glutamic-oxalacetic transaminases were lowered by 33% and 32%, resp. The sedimentation rate and thymol turbidity were decreased, the latter to a lesser degree, while no significant change was observed in serum gamma globulin levels. Serum albumin increased by 10%, as did siderophilin (transferrin) and haptoglobin values. Bilirubinemia decreased 22%, while fecal bilirubin excretion increased 34% and the ratio of conjugated to free bile bilirubin increased 15%. Similarly, sulfobromophthalein retention at 45 min. and its urinary excretion decreased by 23% and 35%, resp. The appearance of hepatic bile was accelerated and the ratio of conjugated to free bile as well as bile conc. were increased by 42% and 39%, resp. Stimulation of enzyme synthesis in liver cell is considered to be responsible for the observed improvement in D-glucuronolactone and glutathione production and the concomitant correction of the hypoalbuminemia. Improved bile flow was also indicated by a 19% reduction of the sulfobromophthalein ratio.

- 9411 ADSORPTION OF TRANSAMINASES ON THE SURFACE OF ERYTHROCYTES IN INFECTIOUS HEPATITIS. (Rus.) Goldberg, L. I. (1st City Hosp., Magnitogorsk, USSR). Vop. Med. Khim. 12(1):45-48, 1966.

Studies on transaminase activity in serum, plasma, whole blood, and RBC suspensions from 37 patients with infectious hepatitis showed it to be 2-3 times higher in suspended RBC than in serum. In addition, the values obtained for transaminases adsorbed on the RBC surface were more closely correlated with the severity of the infection.

- 9412 PRESENCE IN THE INTESTINAL WALL AND CONTENT OF THE INTESTINE OF AXENIC AND NON-AXENIC MICE OF A SUBSTANCE INHIBITING THE INFECTIOUS ACTIVITY OF MOUSE HEPATITIS VIRUS. (Fr.) Piazza, M. (U. Naples, Italy) and J. C. Salomon. C. R. Acad. Sci. (Paris) 262(10)(Ser. D):1159-1162, 1966.

In *in vitro* studies, homogenates of the wall of the ileum or of the content of the small intestine of 3 standard strains of mice had considerable inhibitory effect on mouse hepatitis virus MHV-3. Homogenates of the liver, kidney, spleen or thymus derived from the same animals, did not exert this effect. Although the substance was less active in homogenates derived from axenic mice, sufficient activity was shown to preclude linking it to the intestinal flora or a latent virus infection. The anti-MHV-3 antibody could not be demonstrated in the serum, nor could any other antibody be demonstrated which was active against other murine viruses. The substance was soluble in supernatants of the homogenates. It showed progressively decreased activity in successive segments of the small intestine, approaching zero as these approached the colon. Apparently involved was an enzyme or an association of proteolytic enzymes synthesized by the cells of the intestinal mucosa rather than by the lymphoid cells.

- 3 EFFICIENCY OF DISPENSARY PROCEDURES IN EARLY DIAGNOSIS OF CHRONIC HEPATITIS FOLLOWING EPIDEMIC HEPATITIS. (Rum.) Lăzărescu, V., C. Miron, M. Zamfirescu-Gheorghiu and V. Runcan. Stud. Cercet. Med. Intern. 7(2): 123-133, 1966.

Detailed statistical analysis of 959 persons who suffered infectious hepatitis 1 yr. previously showed that those people who participate in an active outpatient follow-up program (2-8 times annually) can be easily diagnosed as to incipient chronic transformations of their existing condition. Of those regular outpatients whom chronic manifestations were developing 94.4% were detected in the first yr. regular follow-up; practically all (99.1%) were detected after 2 yr. Only 12.6% cases developing chronicity could be identified in noncooperative patients. After 10 yr., about 25% of all chronic conditions occurring in nonparticipating patients remained to be detected. The study shows that cooperation with an active patient program on a large scale is practically the only way of detecting chronic transformations almost as soon as they start developing. Additional data are included to show the relationship between such early diagnosis and various other parameters, such as age, sex, number of symptoms, both subjective and objective, in both the participating and the nonparticipating patient groups.

- 4 OBSERVATIONS ON DEXAMETHASONE THERAPY FOR VIRAL HEPATITIS. (Pol.) Macura, M. (Miejskiego Hosp., Katowice, Poland), A. Grzegorzewska and J. Kowalczyk. Wiad. Lek. 18(15):1213-1219, 1965.

Twenty-one patients with viral hepatitis (with or without cirrhosis), 1 with chronic and 1 with toxic hepatitis (total 33 patients) were treated with dexamethasone. It was concluded that dexamethasone has anti-jaundice action which is only 3-4 times longer than that of prednisone. Definite corticosteroid side effects were encountered. Lymphocytes (mainly neutrophils) and cholesterol levels were increased. Active peptic ulcer constitutes a contraindication to treatment with this agent. Perforation and fatal hemorrhage occurred in 1 of 33 with previous history of peptic ulcer. The authors do not consider that this drug constitutes any real progress in treatment of hepatitis.

- 5 INFECTIOUS HEPATITIS IN CALIFORNIA. A COMMUNITY-WIDE EPIDEMIC. (E.) Maller, H. M. (California State Dept. Public Health, Berkeley), B. Nold, W. H. Clark and H. A. Renteln. Calif. Med. 104(5):352-358, 1966.

An epidemic of infectious hepatitis in a rural California community during 1961, 14 cases were reported in a population of 8166 residents divided into 5272 urban and 2894 rural inhabitants. A sample of 396 cases reported up to Sept. 1 was studied and only about 1 of 3 of these cases could be confirmed in retrospect. However, a number of noteworthy factors emerge from physicians records and reports from the state health department and from a community survey: 1) out of 491 patients known age 72% were at least 20 yr. old. 2) females outnumbered males 280 to 1. 3) residence of 495 patients was 325 urban and 170 rural, attack rates 6.2% and 5.9%, resp. 4) of 20 hospital employees 17 or 18 had illnesses resembling hepatitis. 5) better neighborhoods had a much greater incidence of hepatitis than poorer ones. 6) the disease was most prevalent during the hottest mo. of the yr. 7) the most common symptoms were anorexia, nausea, and dark urine (85%), abdominal pain (78%). A minority showed jaundice. 8) the average duration of the disease was 4.3 wk. 9) some evidence indicated spread of disease from person to person.

- 16 LONG TERM EVALUATION OF POSSIBLE DEVELOPMENT OR CONSEQUENCES OF VIRAL HEPATITIS IN CHILDHOOD. (It.) Ulivelli, A. (U. Florence, Italy), G. Casini Raggi and L. Lecchini. Riv. Clin. Pediat. 76(4-6):359-386, 1966.

The course and possible consequences of disease were evaluated 2 mo.-8 yr. after hospitalization in 49 children (age 2 mo.-12 yr. at the time of hospitalization; 25 males and 24 females) with viral hepatitis. Results of laboratory tests did not differ significantly from those at the time of hospitalization; serum glutamic-pyruvic and pyruvic transaminase levels and bilirubinemia values were normal; serum colloidal lability tests were within normal limits, except in 1 patient with positive MacLagan; total protein values were the same, while gamma globulin levels and the albumin/globulin ratio were normalized. Urine analysis revealed no

pathology. Slight gastrointestinal disturbances (constipation in 4) were observed in 14. No differences were observed in patients treated (23; no details) and not treated (26) with corticosteroids. The case is presented of a 9-yr.-old girl who developed subsequent episodes of jaundice 35 days, 1 yr., and 4 yr. after her first hospitalization despite treatment with corticosteroids, antibiotics, vitamins, and hepatoprotective agents; the most recent biopsy revealed marked cellular polymorphism and chronic hepatitis.

- 9417 SERUM SORBITAL DEHYDROGENASE IN VIRAL HEPATITIS. (It.) Lecchini, L. (U. Florence, Italy), R. Rossi and A. Olivelli. Riv. Clin. Pediat. 76(4-6):286-294, 1966.

Serum levels of sorbital dehydrogenase (Gerlach method), glutamic-oxalacetic and glutamic-pyruvic transaminase, lactic dehydrogenase, and aldolase were determined and compared in 26 children (age 3-12 yr.) with viral hepatitis. Serum lactic dehydrogenase and aldolase determinations showed slight sensitivity and specificity. On the contrary, decreased levels of sorbital dehydrogenase, glutamic-oxalacetic transaminase, and glutamic-pyruvic transaminase were observed in all patients after 7 days of hospitalization. By day 21, serum levels of sorbital dehydrogenase had returned to normal, while those of both transaminases were still slightly elevated. All of the patients had received the same diet and treatment (vitamins B and C and hepatoprotective agents). Results indicate that the determination of serum sorbital dehydrogenase levels is a valuable aid in the diagnosis and prognosis of viral hepatitis.

- 9418 COMPARISON OF BILIRUBINEMIA AND BILIRUBINURIA WITH OTHER TESTS IN THE DIAGNOSIS OF VIRAL HEPATITIS. (It.) Cocchi, R. (U. Florence, Italy) and R. Rossi. Riv. Clin. Pediat. 76(4-6):319-325, 1966.

Results of bilirubinemia (Malloy-Evelyn method) and bilirubinuria (Icotest) tests were compared with those of serum glutamic-oxalacetic and pyruvic-transaminase, aldolase, and sorbital dehydrogenase in 32 children (age 4-12 yr.) with viral hepatitis. All patients had received the same diet and treatment (vitamin B and C; thioctic acid; hepatoprotective agents; liver and pancreas extracts). Among the tests based on serum enzyme determinations, aldolase determination was of less value while transaminase and sorbital dehydrogenase determinations were highly significant. Bilirubinemia values reached a critical point by day 7 after hospitalization; bilirubinuria disappeared from day 7 on. Direct relationship was observed between blood levels of direct bilirubin and urinary levels. Results indicate that urinary bilirubin determination is a rapid test and a valuable aid in the diagnosis and prognosis of viral hepatitis.

- 9419 AN OUTBREAK OF INFECTIVE HEPATITIS TREATED WITH GAMMA GLOBULIN. (E.) O'Donnell, B. (Dept. Med., Kildare Co., Ireland) and W. J. Cowhey. Med. Officer 95(22):291-292, 1966.

Admin. of gamma globulin to all contacts (2.75 ml of a 12% soln.) seemed to control and eventually arrest the spread of infectious hepatitis in a residential college of 600 male students of whom 45 had already become ill. Although the outbreak began 10 days prior to the admin. of gamma globulin, no marked case occurred later than 6 days afterwards and no cases occurred after the 11th day. All but one patient resided in the same building, but the source of the infection remained undetected and was considered to have been contacted during the vacation by some member of the infected building.

- 9420 ACUTE HEPATITIS IN THE DIABETIC. (Fr.) Coppo, M. and G. Di Marco. Journees Ann. Diabet. Hotel Dieu 1966:139-146.

An episode of acute icterogenic hepatitis lasting an av. of 48 hr. before complete disappearance of jaundice was seen in 24 of 1456 diabetic in-patients of a large municipal hospital. Acute anicteric hepatitis was seen in 1 additional patient. The av. duration of illness, prior to the episode, had been approx. 5 yr. Hepatomegaly was demonstrable in 21 of 25 and 14 of 25 had been suffering for some time from anorexia. The cases were distributed over a considerable period of time, without significant clustering, appearing to exclude the likelihood of transmission of

iral infection. Mean values for fasting glucosemia and 24-hr. glucosuria were reased by approx. 40% and 210%, resp., during the episodes, and had failed to urn to prehepatitis levels at the time of a follow-up study of 12 of these pa- nts, 3 yr. after their discharge. Although 21 of 25 were successfully standardized oral diabetic agents prior to the episodes, only 3 of 12 who could be followed e still controlled without insulin 3 yr. later. As compared to the period just ceding the attack of hepatitis, av. insulin requirements had increased by approx. at the time of discharge from the hospital; by a little more than 53%, 3 yr. er. At the latter time, there was also a demonstrable increase of α_2 - and β -glo- ins in all patients followed. Several also showed a sharp increase of γ -globulins 3 showed unmistakable evidence of incipient, chronic sclerogenic hepatitis. It concluded that the original episode probably resulted from a critical, non-specific lure of hepatic resistance and that the sequelae of the episode included a onic disturbance of the metabolic equilibrium predisposing to the development chronic sclerogenic hepatitis.

1 BEHAVIOR OF SOME SPECIES OF BACTERIA IN THE STOOLS OF PATIENTS SUFFERING WITH VIRAL HEPATITIS. (Pol.) Sawaryn, T. (Acad. Med., Bytom, Poland). Przegl. Epidem. 19(4):441-444, 1965.

teriological studies of the feces of 70 patients with viral hepatitis (both sexes, 50 yr. old) were carried out. In 20 cases, diarrhea as well as abdominal pain, sea and vomiting occurred. In 50 cases, the abdominal symptoms were milder, and diarrhea occurred. Bacteriologic comparison of the stools revealed alteration of terial flora among the more symptomatic group and no distinct changes in the cies of fecal bacteria (as compared to normal subjects) in the less symptomatic up. It is concluded that the gastrointestinal symptoms encountered in patients h viral hepatitis are not caused by the viral infection, but by the changes in bacterial flora of the large intestine.

2 HISTOPATHOLOGICAL STUDIES ON THE ETIOLOGY OF VIRAL HEPATITIS IN ANIMAL EXPERIMENTS. (Hun.) Baló, J. (U. Budapest, Hungary), G. Kendrey, M. Selylyei and A. Bajtai. Orv. Hetil. 107(10):443-445, 1966.

atological studies on the transmission of the epidemic hepatitis virus in rats e conducted on livers from 7 rats fed a synthetic normal diet (Group 1); 10 rats a normal diet and infected with hepatitis virus (Group 2); 9 rats fed a diet taining ethionine (Group 3); and 8 rats fed an ethionine-supplemented diet and ected with hepatitis virus (Group 4). No pathologic changes were observed in livers of rats of Groups 1 and 2, nor were there any appreciable differences een the histopathologic findings in the livers of Groups 3 and 4. Results in- ate that in the rat, in contrast to humans and dogs, the virus of infectious atitis does not produce any specific histopathologic changes.

3 NEW DATA ON THE QUESTION OF LIPOPEROXIDATION IN CARBON TETRACHLORIDE POISONING. (E.) Recknagel, R. O. (Western Reserve U., Cleveland, Ohio) and A. K. Ghoshal. Exp. Molec. Path. 5(2):108-117, 1966.

in vivo and in vitro studies of livers from male rats who received CCl_4 (250 $\mu\text{l/g}$) icate that this hepatotoxin increases lipoperoxidation, giving rise to the produc- n of malonic dialdehyde which has a short half-life due to further degradation. s short existence does not allow a conc. sufficient for detection by the thiobar- uric acid (I) reaction which explains why this test has been reported negative viously. This rapid turnover was demonstrated by the inability to recover in ed malonic dialdehyde in incubated rat liver whole homogenates (in saline-phos- te buffer with EDTA). The source of this metabolism was localized in the mito- ndrial fraction and was inactive without ATP, Mg^{++} and inorganic phosphate. The duction of I-positive material by the whole homogenate is depressed by small unts of CCl_4 in vitro. This inhibition does not occur if the homogenate is led before the addition of CCl_4 .

4 VIRAL HEPATITIS IN SUBJECTS WITH MICROCYTERMIA. (It.) Garagnani, A. (U. Bologna, Italy), L. Suriani, C. Brillante and E. Castelli. Arch. Pat. Clin. Med. 42(4):320-334, 1966.

Various blood and liver function tests were conducted in a series of 26 children (male and 12 female; age 3-12 yr.) with viral hepatitis. In 18 of 26 (69.2%), blood studies revealed Silvestroni-Bianco microcythemia; in 6, both parents had the blood disease, while in 12, 1 of the parents did. Routine liver tests showed a greater frequency and persistence of liver impairment among patients with microcythemia, although no correlation was possible between the severity or duration of jaundice and the blood disease. Abnormal sulfobromophthalein, galactosuria, and Quick prothrombin test values persisted even after the regression of hepatomegaly. Results of the tromexan test confirmed the evidence of liver damage observed with the routine liver function tests. In patients with microcythemia, splenomegaly persisted for 2 yr.

Cirrhosis

- 9452 ELECTRON MICROSCOPY OF CIRRHOTIC NODULES. TUBULARIZATION OF THE PARENCHYMA BY BILIARY HEPATOCYTES. (E.) Phillips, M. J. (U. Toronto, Ontario, Canada) and J. W. Steiner. Lab. Invest. 15(5):801-817, 1966.

Electron microscope studies were performed on liver specimens obtained at biopsy from 5 patients with posthepatitis cirrhosis selected because of the abundance of tubularized channels in the hyperplastic nodules. The liver cells forming the tubules had a modified structure and showed marked polarization of their cytoplasmic organelles. They are disposed so that 6 or more cells surround the main lumen of a biliary channel, are frequently separated from neighboring parenchymal cells by connective tissue elements, and are usually invested by a well-defined basement membrane. Since there is adequate reason for considering these cells as structurally intermediate between liver cells and biliary cells, the authors have designated them as biliary hepatocytes.

- 9453 THE KINETICS OF ^{131}I ROSE BENGAL IN NORMAL AND CIRRHOTIC SUBJECTS STUDIED BY COMPARTMENTAL ANALYSIS AND A DIGITAL COMPUTER. (E.) Turco, G. L. (U. Turin, Italy), F. Ghemi, G. Molino and G. Segre. J. Lab. Clin. Med. 67(6):983-993, 1966.

In 15 normal and 10 cirrhotic subjects, derivation of an hepatogram and of the curve of disappearance of radioactive iodine from the peripheral circulation, following i.v. inj. of iodine-labeled tetrabromotetraiodofluorescein (rose bengal), permitted successful discrimination of patients from controls when 4 parameters were considered within the framework of a compartmental model: the transfer constant from the blood to the liver, the transfer constant from the liver to the blood, intrahepatic passage through the hepatic cell to the biliary ducts and fractional outflow from the biliary tract. In practice, the first 2 parameters alone were sufficient to discriminate between the 2 groups, as were the first and last parameters alone. However, the last 3 parameters alone were unable to make such discrimination successfully. As suggested by the foregoing, the most important, single parameter was the transfer constant from the blood to the liver, which also showed good correlation with the rate constant of disappearance of sulfobromophthalein from the blood, in terms of averages for the two groups of subjects but not in terms of individual subjects.

- 9454 CAN PATIENTS WITH CIRRHOSIS BE IMPROVED BY CERTAIN MEDICATIONS WHICH HAVE BEEN RELEASED FOR CLINICAL TRIAL? (Fr.) Camatte, R. (Municipal Hosp., Marseille, France). Sem. Ther. 42(5):298-300, 1966.

In a double-blind study, thiazolidine carboxylic acid, an experimental medication released for clinical trial, was admin. perorally for a mo. to 13 alcoholic and 2 non-alcoholic patients with hepatic cirrhosis. Results of treatment were tabulated as satisfactory (4 cases), partial improvement (5), fair (1) and no response (5). Among 15 patients receiving placebo, 6 showed some degree of improvement (the 1st 3 categories, above) and 9 failed to respond. Tolerance was good in 10 of 15 who were medicated; 3 developed transient diarrhea; 1 developed nausea and vertigo; 1 developed transient, diffuse erythematosis. There were no unfavorable hematologic or renal side-effects. It is noted that serum albumin levels were decreased in 4 patients, increased in 11; serum gamma globulin levels were somewhat increased in 11; prothrombin was increased in 7.

- 9455 RENAL FAILURE WITH CIRRHOSIS. OBSERVATIONS ON THE ROLE OF DIURETICS. (E.) Lieberman, F. L. (John Wesley Co. Hosp., Los Angeles, Cal.) and T. B. Reynolds. Ann. Intern. Med. 64(6):1221-1228, 1966.

Plasma vol. and renal hemodynamics were measured before and after large diureses in 43 patients with cirrhosis placed on sodium restricted diets and after admin. of spironolactone (50 mg twice a day; 40 patients) alone or in combination with hydrochlorothiazide (100 mg twice a day; 11), ethacrynic acid (100 mg twice a day; 25), furosemide (80 mg twice a day; 1), ethacrynic acid and hydrochlorothiazide (2), or ethacrynic acid and furosemide (1); 2 patients received ethacrynic acid alone and 1 received furosemide alone. Av. diuresis was 21 lb. over a 14-day period, and plasma vol. and creatinine clearance showed statistically significant mean decreases of

4% and 10.9%, resp. No change in mean para-aminohippurate clearance was observed in 19 patients tested. Substantial falls in creatinine clearance were observed in patients, all of whom showed a decrease in plasma vol. Creatinine clearance returned to prediuresis levels either spontaneously or with an expansion of plasma vol. associated with increased sodium intake. No patient developed serious renal failure. During the 24 mo. required for this study, an additional 350 patients with cirrhosis and ascites were treated. Severe renal failure developed in 25; 19 of the 25 had not undergone a prior diuresis as judged by wt. loss. It is concluded that drug-induced diuresis is not responsible for the majority of cases of severe renal failure accompanying cirrhosis.

66 **INTESTINAL BACTERIAL STUDIES IN ALCOHOLIC CIRRHOSIS AND CLINICAL CORRELATIONS.** (Fr.) Vachon, A., P. Paliard, R. Tête, A. Sédallian and J. Barthe. Rev. Lyon Med. 15(8):353-362, 1966.

Jejunal flora was studied in patients with cirrhosis of alcoholic origin by protected jejunal intubation (17 patients) and by fecal culture (25). Results of jejunal intubation showed 6 cases with sterile jejunal fluid, 6 with Staphylococcus aureus, 3 with Escherichia coli, 2 with yeast, and 1 with S. albus; jejunal fluid was sterile in 2 hypertrophic and 4 decompensated patients, while bacterial flora was present in 3 hypertrophic and 8 decompensated patients. Among 7 of the above patients not subjected to antibiotic treatment, jejunal fluid was sterile in 2 hypertrophic patients and contained bacteria in 5 (1 hypertrophic and 4 decompensated). Of 6 patients treated with neomycin or colimycin for an av. of 6 days, jejunal fluid was sterile in 4 and contained bacteria in 2; of 4 patients treated with streptomycin (1) or terramycin (3) before intubation, all still contained S. aureus in the jejunal fluid. Fecal examination in 25 patients with alcoholic cirrhosis showed a predominance of proteolytic anaerobic bacteria over the Lactobacilli. The relationship of bacteriologic findings to diarrhea, fever, hemorrhage, and portal thrombosis frequently observed in patients with cirrhosis is stressed. The importance of bacteriological findings in the choice of an antibiotic is discussed.

67 **SEPTICEMIA AND BACTEREMIA IN ALCOHOLIC CIRRHOSIS.** (Fr.) Vachon, A., R. Tête, P. Paliard and J. Malluret. Rev. Lyon Med. 15(8):343-352, 1966. Blood culture studies in 155 patients with febrile cirrhosis of alcoholic origin revealed the following pathogenic bacteria in 34 patients (24 decompensated; 10 with ascites): Escherichia coli (17), E. coli and Streptococcus (2), Streptococcus alone (5), Streptococcus and Staphylococcus aureus (1), S. aureus alone (6), Staphylococcus aureus and Pneumococcus (1), Pneumococcus alone (1), and Listeria monocytogenes (1). Among the contributing factors, diarrhea seems to play an important part, while portal hypertension and shunt favors passage of bacteria from the intestine into the blood stream. Fever is usually of the variable type. Periodic blood culture studies show that the majority of cases with unexplained fever in cirrhosis are related to bacterial infection. In some cases, infection may be controlled by antibiotic therapy, but in the present series, 22 patients died and only 1 responded to treatment.

68 **A GENETIC APPROACH TO THE PATHOGENESIS OF HEPATIC CIRRHOSIS. A CLINICAL AND SEROLOGICAL STUDY.** (E.) Elling, P. (Municipal Hosp., Copenhagen, Denmark), P. Ramløv and P. Bildsøe. Acta Med. Scand. 179(5):527-533, 1966. Serological investigation of 38 probands (24 women and 14 men) revealed the presence of antinuclear factor, rheumatoid factor (latex test), and cytoplasmic thyroid antibodies in 11, 8, and 2, resp., of 13 patients with the posthepatic form; 1, 3, and 0, resp., in 9 with the alcoholic form; 7, 3, and 1, resp., in 14 with the cryptogenic form; 0, 0, and 1, resp., in 2 with the biliary form. Similar studies in 90 full siblings (53 women and 37 men; age 30-79 yr.) revealed antinuclear factor in 22% and rheumatoid factor in 17%, while thyroid antibodies and hypergammaglobulinemia were not more common among the relatives than in 2 control series consisting of 49 spouses of the siblings investigated and 194 blood donors. A positive reaction for antinuclear factor and rheumatoid factor was found in 22 of 42 (52%) relatives of probands with a positive antinuclear factor reaction. No evidence of familial

occurrence of liver cirrhosis was seen in this study. No correlation was observed between the incidence of these reactions in the sibling series and the type of hepatic cirrhosis in the probands.

- 9459 EXCRETION OF PHENOLIC AMINES BY PATIENTS WITH CIRRHOSIS OF THE LIVER. (E.) Dubovsky, J. (Charles U., Prague, Czech.) and J. Petrášek. Rev. Czech. Med. 12(2):98-102, 1966.

In a group of 10 cirrhotic patients, the excretion of methylnorepinephrine, methyl-epinephrine, 3-methoxytyramine, N-methyl-methylepinephrine, and p-tyramine were examined by isolation on polystyrene latex and two-way chromatography on paper. A tendency for a higher excretion of derivatives of norepinephrine (methyl-norepinephrine) and dopamine (3-methoxytyramine) as well as p-tyramine was revealed in about half the patients. The excretion of methylepinephrine was on an av. within the range of normal values; this lowered the ratio of methylepinephrine to methylnorepinephrine. Determination of the excretion of the epinephrine metabolite N-methyl-methylepinephrine showed it to be elevated in 4 of the 6 patients tested. The possible pathogenesis of these changes is discussed.

- 9460 RATE OF ETHANOL COMBUSTION, FOLLOWING INTRAVENOUS ADMINISTRATION, IN CIRRHOTIC PATIENTS. (E.) Filip, J. (Charles U., Prague, Czech.) and J. Hoenigová. Rev. Czech. Med. 12(2):82-91, 1966.

A one-hr. evenly distributed i.v. infusion of 30 g of ethanol in 300 ml of physiological saline was admin. to 10 patients with developed cirrhosis of the liver, confirmed by biopsy or operation, and to 10 healthy control subjects. Specimens of venous blood were collected before the infusion, after its termination, and at subsequent intervals of 60, 90, and 120 min. In all specimens the alcohol content was estimated in triplicate, using the modified Widmark method. The ethanol combustion in g/hr. was calculated for each subject from the total amount of ethanol admin. and the blood alcohol conc. at 60 and 90 min. according to the authors' formula, the derivation of which is presented in the paper. The statistical comparison of both groups revealed that the combustion of alcohol in persons with cirrhosis (av. 5.45 g/hr.) is significantly slower than in normal subjects (av. 7.61 g/hr.). This finding is presented as evidence of the hepatic localization of ethanol combustion in man.

- 9461 THE VOLUME OF HEPATIC BLOOD FLOW IN PATIENTS WITH CIRRHOSIS. (Ger.) Hoffmeister, H.-E. (U. Göttingen, Germany). Acta Hepatosplen. (Stuttgart) 13(3):154-159, 1966.

Measurements of hepatic blood flow and pressure among 13 patients with bronchogenic carcinoma but no evidence of liver disease or dysfunction (aged 33-65; mean age, 53) showed a very wide range of individual variations in both respects, possibly attributable to age, unsuspected circulatory difficulties or the presence of undetected hepatic metastases. Similar measurements among 11 patients with arrested cirrhosis of the liver, 22 with active cirrhosis, 8 with prehepatic block due to thrombosis of the portal artery and 4 with both cirrhosis and portal arterial thrombosis showed a similar, very wide range of individual variations, nor could any significant differences be established as between patients with arrested and patients with active cirrhosis. It is concluded that histologic activity appears to have no significant effect on hepatic circulation.

- 9462 HEPATIC METASTASES AND PORTAL CIRRHOSIS. (E.) Goldstein, M. J. (Mem. Hosp. Cancer Allied Dis., New York, N. Y.), W. J. Frable and P. Sherlock. Am. J. Med. Sci. 252(1):60-64, 1966.

When the 12 patients with hepatic metastases from a group of 31 patients who had both extrahepatic cancer and portal cirrhosis were matched with 2 control patients each in respect to age, sex, corresponding primary tumor and approx. date of necropsy the incidence of hepatic metastases did not differ in the cirrhotic and the non-cirrhotic liver. The incidence was 39% in the 1st group and 40% in the 2nd. All of the cases were taken from 4,166 necropsy protocols of patients over 21 (excluding those with leukemia and hepatoma, as well as postoperative deaths) from a hospital with a population composed primarily of patients with malignant diseases.

- 63 PROBLEMS OF CIRRHOSIS OF THE LIVER AND KINETICS OF PORTAL HYPERTENSION. (E.) Basu, A. K. (S. S. K. M. Hosp., Calcutta, India). Calcutta Med. J. 63(3):71-86, 1966.
- 300 cases of portal hypertension of varied origin seen over a period of 11 yr. 9 were analyzed. The av. age of cirrhosis cases was between 20 and 30 yr., much younger than the av. age in western countries; the incidence of hepatic obstruction is greater in India than in the west. Splenomegaly, in some cases of extreme size, often accompanied portal hypertension. The majority of cirrhosis cases were of the micronodular type. Long term mortality was 27% for all types of operations to relieve portal hypertension. The cases were followed up over many years. In the group receiving the portacaval shunt, the majority of deaths occurred in the first postoperative yr.; this was not true for the other types of surgical procedure. Hemodynamic studies following portacaval shunt showed that venous pressure was reduced by about 6 mm Hg, and the hepatic blood flow reduced by about 30%.
- 64 PROGESTERONE TREATMENT OF THE EDEMATOUS-ASCITIC SYNDROME IN PATIENTS SUFFERING FROM CIRRHOSIS OF THE LIVER. (Rus.) Berezov, V. M. (Inst. Ther., USSR Acad. Med. Sci., Moscow) and A. S. Loginov. Sovet. Med. 29(4):50-55, 1966.

- 74 HAEMODYNAMIC STATE AFTER RECTAL INFUSION OF TRANSUDATE IN LIVER CIRRHOSIS. (Pol.) Słowiński, J. (2nd Clin. Surg., Acad. Med., Wrocław, Poland), T. Bross, E. Rogalski, O. Boder and M. Masiak. Wiad. Lek. 19(7):521-524, 1966.

- 9475 MICROBIOLOGICAL ACTIVITY OF SULFAPROXYLINE-SULFAMERAZINE IN GALLBLADDER BILE FROM PATIENTS WITH GALLSTONE DISEASE. (E.) Christoffersson, E. (U. Gothenburg, Sweden), Y. Edlund, R. Gamklou and L. A. Nilsson. Scand. J. Clin. Lab. Invest. 18(2):254-260, 1966.

No microbiologically active sulfa was demonstrable in the gallbladder bile in 10 of 11 cases of acute cholecystitis who had received 3 times daily 0.75 g of a sulfonamide compound (sulfaproxyline and sulfamerazine, in equal parts) 2-10 days preoperatively. On the contrary, in 6 of 8 cases of primary chronic cholecystitis, microbiologically active sulfa could be demonstrated (disc test) but this represented only 1/5-1/3 of the given dose. Bile alone had no inhibitory action on the growth of the test strain (rabbit duodenal *Escherichia coli*). Sulfaproxyline did not inhibit the test strain in conc. less than 25 mg/100 ml, while the corresponding figure for sulfamerazine was about 0.5 mg/100 ml. These results suggest that the drug's site of action is not in the bile, leaving the alternatives of the gallbladder wall or the duodenum to be investigated.

- 9476 CHOLELITHIASIS INDUCED BY DEHYDROCHOLATE IN MICE. (Fr.) Besancon, F. (Bichat Hosp., Paris), C. Marche, M. Souhard and C. Debray. C. R. Soc. Biol. (Paris) 159(12):2333-2337, 1965.

In mice, the addition of small quantities of the sodium salt of dehydrocholic acid to a normal diet induced cholelithiasis within 4 mo., accompanied by fatty degeneration of the liver and inflammatory and degenerative changes in the mucosa of the gallbladder. The authors suggest that the current practice of prescribing this substance over long periods of time in the treatment of human lithiasis may entail considerable risk.

- 9477 EXPERIMENTAL COMMON BILE DUCT CONDUITS. (E.) Thorbjarnarson, B. (New York Hosp., N. Y.), P. D. Bostrom, G. L. Smith, D. N. Tucker and A. F. Cortese. Arch. Surg. (Chicago) 92(6):818-821, 1966.

Woven, flexible, Teflon conduits (av. diameter 1.1 cm) were inserted between a choledochotomy 3.5 cm in length and the skin of the anterior abdominal wall in 12 healthy mongrel dogs. Two dogs died from postoperative hemorrhage following placement of the conduit. One dog developed a biliary fistula at the site of the conduit, clinical jaundice, and alcoholic stools; at autopsy, a stricture was found in the distal common duct and the liver was engorged due to biliary stasis and fibrosis. In 9 dogs, complete healing of the common bile duct and reestablishment of biliary flow to the intestine occurred at the end of the experimental period without the development of bile peritonitis, stricture, fistula, infection, hemorrhage, or ileus. Postmortem examination revealed grossly normal biliary trees and livers. Results indicate that in dogs a conduit of sufficient size for duct exploration may be constructed and removed without untoward sequelae.

- 9478 CHRONIC BILIARY OBSTRUCTION. THE RESULTS OF CELLOPHANE WRAPPING OF THE BILE DUCTS IN DOGS. (E.) Dass, R. (Govt. Coll. Med., Patiala, India) and A. Chandra. Indian J. Surg. 28(1):42-49, 1966.

The effects of chronic biliary stasis on the hepatobiliary system were studied in dogs in which a narrow band of laminated cellophane paper was loosely wrapped around the supraduodenal portion of the common bile duct (14 dogs; Group 1); the middle portion of the cystic duct (4 dogs; Group 2); both ducts (5 dogs; Group 3). Complete biliary obstruction was observed in 7 animals of Group 1 and 3 of Group 3; the lumen of the strictured portion was almost completely obliterated in 3 animals and narrow but patent in 1 of Group 2. Progressive jaundice occurred in 9 of 10 animals with complete biliary obstruction; progressive or transient jaundice was seen in 6 of 9 animals with incomplete obstruction. Ascites occurred in 2 patients with incomplete and 1 with complete obstruction. In animals of Group 3, biliary obstruction appeared earlier and were more severe than in animals with single duct obstruction. Prolonged obstruction of the cystic duct caused symptoms resembling those of common bile duct obstruction. Spontaneous restoration of bile duct continuity by invagination of the stricture into the proximal dilated portion occurred in 35% of animals, but only few of them showed improvement in obstruction symptomatology.

- 79 ROUTINE CHOLANGIOGRAPHY DURING BILIARY TRACT OPERATIONS; TECHNIC AND UTILITY IN 200 CONSECUTIVE CASES. (E.) Letton, A. H. (Georgia Baptist Hosp., Atlanta) and J. P. Wilson. Ann. Surg. 161(1):116-119, 1966.
- A new technic for cholangiography is described which permits preoperative X-ray demonstration of the number and location of stones as small as 2 mm in diameter. In initial clinical trials, cholangiographic examinations of 174 consecutive patients resulted in 4 "false positive" and no "false negative" findings. The former, all of which occurred in patients studied at the start of the series, were confirmed at surgery. Surgical exploration of the common duct was avoided in 78% of the cases presenting with classic indications for such exploration and common duct stones were found in 6 patients in whom there were no other indications for opening the duct. The av. time required by the procedure was 5 min., 22 seconds. There were no instances of subsequent pancreatitis or other complications of any kind.
- 80 ACTION OF SOME SPASMOLYTIC AGENTS ON THE ISOLATED BILE DUCT. (E.) Crema, A. (U. Pavia, Italy), G. Benzi, G. M. Frigo and F. Berte. Arch. Int. Pharmacodyn. 161(1):116-119, 1966.
- The antispasmodic activity of selected spasmolytic and parasympatholytic agents was tested on calf terminal bile ducts. Two antagonists were used at conc. able to reduce basal flow through the ducts by 50%: barium chloride (4.4 $\mu\text{g/ml}$) and carbachol (0.11 $\mu\text{g/ml}$). Log dose response curves were collected for each compound studied yielding relative potencies in blocking barium chloride spasm: papaverine 1; phenethamine 0.23, diprophylline 0.02, and Na nitrite 0.009. The parasympatholytic relative potencies for blocking carbachol spasm: atropine 1, oxyphencyclimine 2.25, propenziline 0.004 and diphemanil 0.017. Since relative potency of spasmolytics was shown to vary with experimental situation and reversions of potency occurred with different tests, the best screening method would appear to be the in situ method.
- 81 CHOLESTASIS IN RATS INDUCED BY TAUROLITHOCHOLATE. (E.) Javitt, N. B. (New York U. Sch. Med., N. Y.). Nature (London) 210(5042):1262-1263, 1966.
- In male Wistar rats, infusions of taurocholate for 30-60 min. (0.07-0.48 $\mu\text{M/min./100 g wt.}$) always caused an increase in bile acid excretion. In contrast, similar infusions of tauroolithocholate always caused cholestasis. However, infusion of equimolar amounts of taurocholate together with tauroolithocholate invariably increased bile acid excretion. Chromatographic analysis of the bile samples showed taurocholate and taurochenodeoxycholate. Hyperbilirubinemia occurred during prolonged infusions of tauroolithocholate (0.2 $\mu\text{M/min./100 g wt.}$ for 1 hr., followed by 50% of this rate for 19 hr.). Chromatographic analysis of the azo pigments revealed azo B (glucuronide) and azo A (unconjugated).
- 82 ULTRASONIC DIAGNOSIS OF CHOLELITHIASIS. (E.) Tala, P. (Cent. U. Helsinki Cent. Hosp., Finland), J. Lieto, T. Kerminen and E. Laustela. Ann. Chir. Gynaec. Fenn. 55(2):124-128, 1966.
- A preoperative examination of 33 gallbladder patients with a cholecystography and an ultrasonic echo technic allowed evaluation of these two diagnostic methods. The ultrasonic technic gave a positive stone echo in 79% of the cases, while cholecystography showed stones in 67%. The findings at operation were negative in 5 cases, of which 3 were positive with the ultrasonic technic and cholesterosis or fibrosis was actually present; whereas, with cholecystography there were 2 false positives and 3 instances where the gallbladder did not fill with contrast medium.
- 83 BILE-DUCT PROSTHESES AND ANTI-INFLAMMATORY HORMONES. EXPERIMENTAL STUDY. (Fr.) Garcia Diaz, S. (U. Seville, Spain) and M. Torres Cansino. Lyon Chir. 62(2):229-236, 1966.
- In partially cholecystectomized dogs, the remaining stumps of the common bile duct were anastomosed to a knitted Dacron tube. No operative or postoperative complications occurred in 6 of 10 dogs. In 2 survivors used as controls, severe fibrosis developed, extending as far as the pancreas and the liver without invading either organ. Prednisone or prednisolone postoperatively appeared to totally suppress this reaction without interference with wound-healing or formation of adhesions in the survivors. Histologic studies indicated no pancreatic abnormalities, a moderate degree of hepatic cholestasis. Maximal survival among treated animals was 16 mo.

- 9484 THE VALUE OF HISTOLOGIC DIAGNOSIS IN PATIENTS WITH ODDITIS. (Fr.) Mart E. (Bichat Hosp., Paris), J. Barge and C. Marche. *Ann. Chir.* 20(5-6): 321-326, 1966.

Biopsies of the Sphincter of Oddi, performed on 71 patients, proved to be unsatisfactory from the point of view of both diagnosis and differential diagnosis. It is frequently difficult or impossible to distinguish pathologic sclerotic lesions from essentially normal accentuations of supportive connective tissue. Specimens were characteristic only for the very small area which was sampled immediately and it was impossible to determine whether sclerotic areas were a cause or result of the biliary and pancreatic lesions frequently associated with them. It was equally impossible to predict whether sclerotic processes in this area would prove reversible or irreversible. It is concluded that biopsy makes no significant contribution to diagnosis in patients with Odditis and fails to distinguish between organic and functional disturbances occurring in this region.

- 9485 LITHIASIS IN THE COMMON BILE DUCT IN ELDERLY PATIENTS. OPERATIVE MORTALITY AND CHOICE OF SURGICAL PROCEDURE. (Fr.) Moreaux, J. (Bichat Hosp., Paris) and P. Dufour. *Ann. Chir.* 20(5-6):353-356, 1966.

Among 89 elderly (60-73 yr. old) patients undergoing simple cholecystectomy, the operative and postoperative mortality rate was 1.1%. Among 95 in whom the same operation was accompanied by choledochotomy or choledochotomy and sphincterotomy, the mortality rate rose to 10%. Among 16 in whom it was accompanied by choledochoduodenal or choledochojejunal anastomosis, there were no fatalities. Because of the surgical complexity and the operative time involved, choledochojejunal anastomosis was avoided whenever possible. In general, among patients undergoing choledochotomy the mortality rate among patients over 70 was approx. double the rate seen among patients in their 60's. Death among patients over 70 was invariably due to cardiac, respiratory or "general" complications, rather than any complication resulting from the surgery directly. It is concluded that radical choledochotomy should be avoided in elderly patients whenever it is possible to do so.

- 9486 REPAIR OF BILE DUCT STRICTURES. (E.) Child, C. G. III (U. Michigan, Ann Arbor) and S. M. Lindenauer. *J. Mich. Med. Soc.* 65(6):454-456, 1966.

Of 52 patients treated for bile duct stricture by multiple operation, excellent results were obtained in 73%. The operations were conducted between 1959 and 1964 and the av. follow-up period was 20 mo. The preferred method of repair (used in 56% of these patients) was a Roux-en-Y hepatico-jujunostomy which was usually fashioned in an end-to-side manner with the jejunal limb placed in a retrocolic position. The vast majority, 80.7%, of the strictures resulted from an operative injury during the course of a cholecystectomy. In all, 13% of these patients died and of these 5.7% were operative deaths and 5.7% were deaths related to the biliary tract disease.

- 9487 EXPERIMENTAL CHOLELITHIASIS IN RABBITS FED VARIOUS PROTEINS AND FATTY ACIDS. (E.) Borgman, R. F. (Clemson U., S. C.) and F. H. Haselden. *Arch. Path. (Chicago)* 82(1):72-76, 1966.

Cholesterol gallstones were found in each of 7 groups of 10 rabbits (5 male, 5 female) fed a purified diet containing 40% protein and 10-20% fat for 12 weeks. The diets of the first 4 groups contained 40% egg albumin, lactalbumin, casein, or *Torula* yeast and 20% semipurified oleic acid; those of the other 3 groups contained 40% casein with 20% semipurified linoleic acid, 10% oleic acid, or 15% oleic acid as the fat source. Varying the type of protein fed resulted in the following conclusions: casein was associated with large amounts of gallstones, lactalbumin and *Torula* yeast with moderate amounts, and egg albumin with small amounts. Gallstone formation was comparable in rabbits fed a diet containing 40% casein and 20% of either oleic or linoleic acid. Lowering the oleic acid content from 20% to 10% reduced gallstone formation, but the diet containing 15% oleic acid resulted in the same amount of gallstones as that containing 20% of the acid. Fatty acid percentages in the liver, determined from dried ether extracts, were found to be influenced by both the dietary protein and fat; the effects of protein may have been non-specific since the general condition of the rabbits was much better with casein than with the other proteins in the diet.

- 488 BENIGN POSTOPERATIVE JAUNDICE, A FORM OF INTRAHEPATIC CHOLESTASIS. (Ger.) Schmid, M. (U. Zürich, Switzerland) and M. L. Hefti. Zschr. Gastroent. 4(2):89-95, 1966.

Following prolonged operations which involved unusually extensive or debilitating surgery, 16 patients developed a postoperative syndrome consisting of jaundice and hyperbilirubinemia in the absence of significant histologic changes in the liver. No consistent changes were evidenced in terms of serum phosphatase or serum transaminase activity, or in the blood picture. However, during the period of observable jaundice, which began on the 1st to 10th postoperative day and lasted approx. 2 wk., without fever or cutaneous irritation, the sulfobromophthalein test yielded frankly pathologic results. Biopsy and autopsy findings confirmed extensive intrahepatic cholestasis without evidence of infection or inflammatory process. The syndrome was ascribed to a transient, liver secretory insufficiency whose pathogenic mechanisms could not be defined successfully.

- 489 CARDIOVASCULAR EFFECTS DUE TO TRAUMATIZATION OF THE BILIARY TRACT. (Hun.) Benyo, I. (U. Budapest, Hungary) M. Ihasz and M. Refi. Magy. Sebesz. (2):110-114, 1966.

A rapid pressure increase of 40-50 mm Hg produced in the common duct of anesthetized dogs by an inserted glass catheter resulted in an immediate 20-30 mm Hg drop in arterial blood pressure. Equalization and rebound occurred even before the artificially induced pressure has been relaxed. The same phenomenon was observed upon simple palpation or manipulation of the gallbladder. Ligation of the hepatic duct in order to prevent pressure increase in the intrahepatic spaces did not abolish this response; neither did intraabdominal bilateral vagotomy with Novocaine infusion of the area (of the X.). However, bilateral vagotomy followed by Novocaine block of the coeliac ganglion prevented the pressor effect. Adverse cardiovascular effects which could occur during surgery in the liver area may be effectively prevented by blocking of the coeliac ganglion.

- 490 LDH ISOENZYMES IN CLINICAL PRACTICE. II. THERMOLABILE LDH FRACTION IN BILIARY DISEASE. (Cz.) Kocán, J. and M. Engliš. Cesk. Gastroent. Vyz. 20(2):96-100, 1966.

The thermolabile lactic dehydrogenase (I) fraction was determined in 19 control subjects, 20 with asymptomatic cholelithiasis, 20 with biliary colic, 27 with obstructive icterus, 29 with biliary and gallbladder inflammations, and 11 with cholecystopathy with pancreatitis. No increase of I activity was found in the patients with asymptomatic cholelithiasis; an increase was found in 85% of the remaining (87) patients.

- 491 HYPERBILIRUBINEMIA DUE TO HYPOXIA. (E.) Shibata, Y. (Kyushu U., Fukuoka, Japan). Kyushu J. Med. Sci. 15(4):87-94, 1964.

In a state of hypoxia, the isolated rabbit liver uptake for crystalline bilirubin (sodium salt of bilirubin) and for icteric serum bilirubin was quite different. In the hypoxic condition the liver seemed incapable of clearing icteric serum bilirubin from the perfusate, while the clearance of the sodium salt was unaffected. A case history of a 43-year-old woman further suggests that hypoxia secondary to anemic cardiac failure was one factor (via the property noted in the rabbit studies) in the development of marked hyperbilirubinemia. When the heart insufficiency was treated with blood transfusion and digitalis, the total bilirubin level eventually decreased from 15.7 mg to 1.7 mg/100 liters and the hemoglobin went from 58% (Sahli) to 88%.

- 492 ORAL CHOLECYSTOGRAPHY WITH SH 514 AND SH 550. (320 CASES.) (Fr.) Delahaye, R. P., R. Jolly, P. Boursiquot, J. Laaban and G. Gueffier. J. Radiol. Electr. 47(5):243-247, 1966.

Two new peroral opacifiants were assayed with a total of 320 patients undergoing cholecystography (age range, 17-67; 286/320, male; 0/320 jaundiced). Employed were the sodium salt of β -(3-dimethylaminomethylamino-2,4,6-triiodophenyl) propionate (Biloptine; SH-514), containing 61.4% iodine, or the calcium salt (Solubiloptine; H-550), containing 61.7% iodine. When admin. p.o., 6 g, single dose, 10-12 hr.

prior to attempted visualization of the gallbladder and related structures, results were at least as satisfactory as those obtained with traditional agents. Opaque residues in the small intestine or colon were negligible and did not interfere with interpretation of films. The drug was not suited to accelerated cholecystography (e.g., 2.5-5 hr. after admin.). It was uniformly well tolerated.

- 9493 PATHOGENESIS OF JAUNDICE IN INFLAMMATORY CARDIAC VALVULAR DISORDERS AND FULMINATING BACTERIAL ENDOCARDITIS. (Sp.) Jipp, P. (U. Kiel, Germany). Arch. Enferm. Corazon. 68(1):17-28, 1965.

Autopsy study of 89 patients with endocarditis (31 of 89 jaundiced) confirmed that the jaundice which is frequently seen in these patients was associated with hyperbilirubinemia secondary to a toxic hemolytic process and hepatic retention of bilirubin due to foci of cellular necrosis. These hepatic cellular lesions, in turn, were attributed to circulatory disturbances of cardiac origin.

- 9494 PATHOGENESIS OF CALCIUM BILIRUBINATE GALLSTONE: ROLE OF *E. coli*, β -GLUCURONIDASE AND COAGULATION BY INORGANIC IONS, POLYELECTROLYTES AND AGITATION. (E.) Maki, T. (Tohoku U. Sch. Med., Sendai, Japan). Ann. Surg. 164(1):90-100, 1966.

Both stagnation, often caused by infestation by intestinal parasites, and infection of bile, especially with *Escherichia coli*, together with dietary deficiencies appear to induce formation of calcium bilirubinate stones which are common in the Asian area (currently representing about 30% of all gallstones reported in Japan). Bilirubin glucuronide is hydrolyzed into free bilirubin by the enzyme β -glucuronidase which originates from bacteria. The free bilirubin then combines with calcium in the bile and separates from the bile as calcium bilirubinate particles. These particles are negatively charged and undergo loose coagulation as a result of electrostatic effect of inorganic ions and bridging action of high-molecular-weight organic substances. The coagulate then consolidates more tightly under the influence of physical movement. This hypothesis of stone formation was supported with an *in vitro* model which produced solid stone-like concretions which resembled the amorphous pigmented calcium stones in man.

- 9495 INITIATING FACTORS OF GALLSTONES, ESPECIALLY CHOLESTEROL STONES. II. (E.) Hikasa, Y. (Kyoto U. Sch. Med., Japan), T. Kuyama, I. Maruyama, M. Yoshinaga, M. Hirano, T. Eguchi, R. Shioda, H. Tanimura, K. Hashimoto, H. Muroya and M. Togo. Arch. Jap. Chir. 34(6):1430-1461, 1965.

The formation of cholesterol stones may broadly be considered as due to imbalance between hepatic synthesis and destruction of cholesterol. Deficiency of pyridoxal phosphate and vitamin K as a result of an abnormal shift in bacterial flora of the intestine has been thought to cause this imbalance. However, in experimental animals an increased intake of saturated fatty acids, especially the lower fatty acids is also required for stone formation, even when there is deficiency of pyridoxal phosphate and vitamin K. Qualitative and quantitative changes in bile acids are more important in causing precipitation of cholesterol than alterations in the quantity of lecithin. Pyridoxal phosphate is involved in essential fatty acids (I) metabolism and in hepatic synthesis of bile acids as well as in cholesterol metabolism. Synthesis of bile acids increased in the liver of experimental animals only if both I and pyridoxal were admin. simultaneously. It therefore appears that an increased intake of highly unsaturated fatty acids together with the proper vitamins might serve as a protection against formation of cholesterol stones. There is some relationship (as yet unclear) between adrenocortical functions and I metabolism.

- 9496 FAILURE OF CORTICOSTEROID TEST IN THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE. (E.) Loutfi, G. I. (Boston Hosp. Women, Brookline, Mass.) and R. H. Groves. J.A.M.A. 197(1):48-49, 1966.

A dramatic and sustained response to prednisone therapy in a patient with intrahepatic obstruction, with massive and almost total replacement of the liver with metastatic tumor, is presented. The patient had undergone a radical mastectomy because of carcinoma. She was apparently well for a year, but returned to the hospital because of anorexia, nausea, vomiting and marked asthenia. Physical, hematological and

biochemical findings, with 2 or 3 relatively minor exceptions, were normal. Shortly after admission the patient became markedly jaundiced and her caloric intake became almost nil. Therapy with prednisone resulted in progressive clearing of jaundice and a striking improvement in appetite. She became ambulatory and felt well. The prednisone dosage was tapered off prior to discharge. Subsequently her condition deteriorated rapidly. Weakness and jaundice returned; ascites and splenomegaly appeared. Despite vigorous treatment lethargy and coma ensued within a week. Death occurred 45 days after the 2nd admission. Autopsy showed an enlarged liver which weighed 4000 g. The appearance was that of massive diffuse replacement by metastatic tumor of 90% of the liver tissue. No other metastatic disease was found. The authors discuss possibilities which might be responsible for the striking effects of prednisone in this patient.

 CORTICOSTEROID: 8453*, 8468*, 8487, 8490, 8508, 8552*, 8652, 8728, 8904, 9040*, 9144, 9410*, 9414*, 9472, 9496*
 CROHN'S DISEASE (see Enteritis, regional)
 CYSTIC FIBROSIS (see Mucoviscidosis)

DIAGNOSTIC PROCEDURES (see under Gastrointestinal tract; specific organs and disease)
 DIAPHRAGM: 8742
 DIARRHEA: 8516*, 8525, 8661, 9012, 9030, 9034*, 9063, 9088, 9089, 9104
 DIGESTION (see also Bile; Intestine, Small; Pancreas): 8376*, 8416*, 8418*, 8419*, 8420*, 8421*, 8422*, 8423*, 8428, 8432, 8433
 lipid: 8957*
 DIVERTICULA (see under specific organ; Malabsorption)
 DIVERTICULITIS (see under specific organ; Malabsorption)
 DUMPING SYNDROME (see Gastrectomy, complications, dumping syndrome)
 DUODENUM (see also Intestine, Small): 8321*, 8348*, 8349*, 8607, 8691, 8914, 8923, 8936, 8941, 8953*

DUODENUM (Contd.)
 diseases (see also under Ulcer): 8545, 8901, 8924, 8931
 diverticula: 8912
 morphology: 8355*, 8356*
 DYSENTERY (see also Amebiasis; Shigellosis; Typhoid Fever): 8562*, 8576, 9080
 epidemiology: 8582, 8695
 treatment: 8614

EMBRYOLOGY (see Growth and Development)
 EMESIS (see Vomiting)
 ENDOSCOPY (see also under specific organ, diagnosis)
 ENTERITIS (see also Colitis; Enterocolitis; Gastroenteritis): 8714
 ENTERITIS, Regional: 8988*, 8989, 8990, 8991, 9130*, 9131*
 ENTEROCOLITIS (see also Colitis; Gastroenteritis)
 8627
 pseudomembranous: 9064
 staphylococcal: 8523*
 ENZYMES, MISCELLANEOUS (see also Amylase; Liver, enzymes, parenchymal; Pancreas, secretion; Phosphatase; Stomach, secretion, pepsin): 8329*, 8330*, 8333*, 8336, 8364*, 8420*, 8421*, 8423*, 8430, 8437*, 8438*, 8503, 8609, 9175, 9324, 9327
 ESOPHAGITIS: 8738*, 8760, 8775
 ESOPHAGUS (see also under Achalasia; Hernia)
 anomalies: 8746, 8762
 cancer: 8750, 8763, 8765, 8770, 8777, 8780
 diagnosis: 8735*, 8769
 esophagoscopy: 8747
 manometry: 8758
 radiology: 8770, 8771
 diseases: 8754
 diverticula: 8744, 8772, 8783
 fistula: 8745, 8762, 8782
 foreign bodies: 8767
 morphology: 8370, 8739*
 motility: 8436*, 8444*, 8449*, 8737*, 8740*, 8741, 8752, 8774
 prosthesis: 8742, 8757, 8778, 8779, 8880
 stricture: 8736*
 surgery: 8750, 8753, 8771
 varices: 8764

FAT (see Absorption, lipid; Digestion; Liver, metabolism; Malabsorption)
 FECES: 8324*, 8529, 8540, 8541, 8593, 9099, 9113
 FISTULA (see also under individual organs): 9078, 9082, 9517

GALLBLADDER (see also Biliary Tract; Cholecystitis; Cholelithiasis)
 anomalies: 9498, 9511, 9518
 cancer: 8547*, 9512, 9533, 9550
 cholecystokinin (see also Pancreas, pancreozymin): 8439*
 diagnosis: 8532
 cholecystography: 9482*, 9492*, 9507
 diseases: 9476*, 9521, 9545, 9547
 function: 8330*, 8390
 morphology: 8363*
 surgery: 9483*, 9485*, 9531, 9542

RECTOMY (see also Malabsorption; Ulcers, surgery; Stomach, cancer): 8790*, 8827, 8828, 8851, 8854, 8857, 8860, 8865, 8875, 8947*, 8957*, 8971, 8975
complications: 8869, 8870, 8879, 8949*, 8964, 8980
dumping syndrome: 8451, 8888*, 8968
malabsorption: 8375*, 8382*, 8797*, 8873, 9005*
microorganisms: 8791*
treatment: 8802*
technic: 8789*, 8802*, 8812*, 8878
RIN (see Stomach, gastrin)
RITIS: 8843, 8849
associated disease: 8795*, 8796*, 8962*
diagnosis: 8807*
etiology: 8794*, 8795*, 8796*, 8962*
experimental: 8798*
treatment: 8536, 8539, 8545, 8875
ROENTERITIS (see also Colitis; Enteritis; enterocolitis): 8516*, 8617, 8618, 8621, 8657, 8698
ROINTESTINAL TRACT (see also specific organs; cancer)
associated diseases: 8339, 8580, 8590, 8600, 8619, 8663, 8686, 8697, 8724, 8730
cancer: 8645, 8648, 8660, 8677, 8688, 8690
cardiovascular system: 8673
development: 8420*, 8421*, 8428
diagnosis: 8517*, 8527, 8609, 8648, 8658, 8660, 8679, 8688, 8690, 8861
biopsy: 8693
radiology: 8519*, 8533, 8535
disease: 8542, 8573, 8574, 8613, 8656, 8717, 8730, 8741

Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, cause, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

PRE-CLINICAL SCIENCES

GENERAL

- 53 URINARY AMINES OF INTESTINAL BACTERIAL ORIGIN. (E.) Perry, T. L. (U. Brit. Columbia, Vancouver 8, Canada), M. Hestrin, L. MacDougall and S. Hansen. Clin. Chim. Acta 14(1):116-123, 1966.
- The urinary excretion of amines was studied in 2 normal subjects and in 2 chronically hospitalized patients before and after ingestion of antibiotics which altered the intestinal flora. All subjects consumed a strict diet, free of all substances of plant origin for at least 72 hr. prior to urine collection and for the duration of the tests. In addition, no cheese was consumed; no drugs, except those listed below, were taken. Vanilla extract and histamine were given to both normal subjects and tryptophan to one of them to provide precursors of certain amines. After 24-hr. control urine sample, one received succinylsulfathiazole and neomycin for 1 1/2 days. After 4 1/2 days ingestion of vanilla extract and histamine was repeated and a 24-hr. urine collection made. The second subject after control urine collection received succinylthiazole only for 4 days followed by ingestion of vanilla extract, histamine and tryptophan prior to 24-hr. urine collection. The two hospitalized patients were given a monoamine oxidase inhibitor, phenelzine, daily for 12 days. A 24-hr. control urine sample was taken on day 7 of treatment, followed by daily dosages of neomycin, ampicillin and nystatin for 5 days. On the 12th day 24-hr. urine samples were collected. Urinary amines were quantitatively determined by chromatography. Evidence was obtained that 5 amines which are usually present in human urine are largely, if not entirely, of intestinal bacterial origin. These are tryptamine, p-tyramine, octopamine, N-acetylhistamine, and peridine. Three unidentified ninhydrin-positive amines often present in urines of hospitalized mental patients were markedly reduced in the urines of the two chronically hospitalized patients as a result of intestinal chemotherapy. Intestinal bacteria, drugs and various items in the diet constitute exogenous sources of urinary amines.
- 54 CELLULAR LOCALIZATION OF MONOAMINE OXIDASE IN RAT SALIVARY GLANDS. (E.) Almgren, O. (U. Goteborg, Sweden), N. E. Andén, J. Jonason, K. A. Norberg and L. Olson. Acta Physiol. Scand. 67(1):21-26, 1966.
- Adult rats of both sexes were used in three groups: in Group 1 sublingual and maxillary ducts were ligated near the hilum of the gland; in Group 2 the glands were preganglionically sympathectomized by removal of 1 cm of cervical sympathetic trunk; in Group 3 postganglion sympathectomy was done by removal of the superior cervical ganglion. These operational procedures were again unilateral, the intact side serving as a control. Duct ligation caused a marked reduction in the wet wt. of the glands with atrophy of parenchymal cells. The atrophy was not accompanied by loss of norepinephrine as was proved by biochemical tests and histochemical evidence. Monoamine oxidase activity was sharply reduced after duct ligation. Enzymatic activity was tested by 3 methods: (1) in terms of O₂ consumption using tyramine as a substrate; (2) by dihydroxyphenyl acetic acid formed from tyramine; and (3) by fermentation of p-hydroxyphenylacetic acid from tyramine. Denervated glands showed only a slight decrease in monoamine oxidase activity and histochemical tests showed no difference between control and denervated glands.
- 55 EFFECTS OF PANCREOZYMIN, URECHOLINE AND ACTINOMYCIN D ON THE METABOLISM OF RIBONUCLEIC ACID BY CANINE PANCREAS. (E.) Yang, J. (U. Utah, Salt Lake City) and S. R. Dickman. Biochem. J. 100(2):548-555, 1966.
- In canine pancreatic slices, C¹⁴-orotic acid incorporation was very rapid into cytoplasmic 4S RNA (probably representing end-group turnover), but no label incorporation into cytoplasmic ribosomal RNA was seen. Nuclear 50S RNA showed two E₂₆₀ peaks upon sucrose gradient centrifugation, at 18S and 28S; these were only slightly labeled. Highly labeled material had sedimentation coefficients in the range 35-45S. Nuclear 65S RNA had an E₂₆₀ peak at 16S; the highest specific labeling of any nuclear RNA fraction was seen in the 25-35S fraction. The 50S, 65S, and 80S RNA fractions all possessed a ribosomal composition, and therefore probably contained predominantly ribosomal precursor RNA. Actinomycin D (0.5 µg/ml) inhibited C¹⁴-orotic acid incorporation into both nuclear fractions, but not into cytoplasmic 4S

GENERAL

RNA. Urecholine and pancreozymin both inhibited incorporation into the heavy nuclear RNA fractions of high specific activity, but did not inhibit metabolism of the ribosomal precursor type of nuclear RNA. These agents also caused moderate inhibition of orotic acid incorporation into cytoplasmic 4S RNA.

- 9556 TOXICITY OF BETAZOLE HYDROCHLORIDE FOR THE PERTUSSIS-SENSITIZED MOUSE. (E.) Malkiel, S. (Memorial Hosp., Worcester, Mass.) and B. J. Hargis. Proc. Soc. Exp. Biol. Med. 122(1):685-686, 1966.

The LD₅₀ of betazole hydrochloride for CFW mice which have been inj. i.p. with 6×10^9 Bordetella pertussis phase 1 cells 4 days previously is about 80 times that for histamine. The LD₅₀ of histamine phosphate was 0.027 mg/g for the pertussis-sensitized mice and 0.807 mg/g for the control, unvaccinated mice. The LD₅₀ for betazole did not differ significantly between the vaccinated and the unvaccinated mice. However, a chronic toxicity to betazole was demonstrated at the LD₅₀ and lower levels where the death rate approached 90% at 96 hr. following a single inj. This death probably resulted from something other than a histamine-like shock as it appears that betazole has negligible histamine-like action.

- 9557 ON THE COLLAGENOLYTIC ACTIVITY OF THE MAMMALIAN PANCREAS. (E.) Hakim, A. A. (Armour Pharm. Co., Kankakee, Ill.). Enzymologia 30(5):299-329, 1966.

The specific hydrolytic activities of a bacterial collagenase and certain Bridase extracts are compared to the specific actions of a partially purified pancreatic enzyme AL0534. The bacterial enzyme hydrolyzed bovine corium collagen, steerhide collagen, a hexapeptide and weakly hydrolyzed glycyl-L-tyrosine amide. The pancreatic enzyme AL0534 hydrolyzed bovine corium collagen, steerhide collagen, the hexapeptide, and L-prolylglycine. Bridase extracts showed weak activity on steerhide collagen and hydrolyzed the hexapeptide and a number of di-, tri-, and tetrapeptides. The 3 enzymes showed differences in products giving the ninhydrin test. Tryptic digestion of collagen does not yield substances giving a positive ninhydrin test.

- 9558 PANCREATIC CARBOXYPEPTIDASES: ACTIVITIES IN ZINC-DEFICIENT RATS. (E.) Hsu, J. M. (Johns Hopkins U., Baltimore, Md.), J. K. Anilane and D. E. Scanlan. Science 153(3738):882-883, 1966.

Young male rats (50-70 g) were divided into 2 groups. Group 1 received a diet low in zinc; Group 2 received the same diet supplemented daily with 150 µg zinc sulfate. The wt. gain over 103 days averaged 57 g for rats receiving the zinc-poor diet and 265 g for the controls. Other zinc deficiency symptoms included graying of black hair, alopecia, and scabby skin lesions. After 103 days the animals were sacrificed and the cleaned pancreatic glands frozen at -20°. The frozen glands were broken up, homogenized, dehydrated, and defatted in the cold. The powdered gland was extracted with cold distilled water (50 ml/g of powder) for 15 min. then centrifuged. The supernatant was tested for activity of the zinc-containing enzymes, carboxypeptidase A, carboxypeptidase B, and liver alcohol dehydrogenase. Only carboxypeptidase A showed any decreased activity (approx. 1/3) in animals with low zinc diet as compared to controls.

- 9559 PRODUCTION AND INHIBITION OF GAS IN VARIOUS REGIONS IN THE INTESTINE OF THE DOG. (E.) Richards, E. A. (U. Illinois, Urbana) and F. R. Steggers. Proc. Soc. Exp. Biol. Med. 122(2):573-576, 1966.

Dewormed female mongrel dogs (av. wt. 12.8 kg) fasted for 24 hr. were anesthetized and incised for 10 cm in the abdominal midline. Intestinal segments 50 cm long, isolated by ligation, were prepared in the duodenum, upper jejunum, lower ileum and colon (only 40 cm long). Cannulae fitted with adapters were placed at each end of the 4 segments so that a segment could be closed off or coupled to a gas collection apparatus. To record the amount of gas production and the degree of inhibition (due to pretreatment of animals with antibiotics) in the 4 segments of the intestine, 3 different series of experiments were performed using 2 different homogenates: (1) bacterially inert methyl cellulose, (2) bean in untreated animals, (3) bean in antibiotic-pretreated animals. The existing gas in the segments was

ushed out prior to inj. of the homogenate (50 ml per segment). Gas volumes were recorded for each segment 3 hr. after inj. of homogenate and the composition of the gas was determined. No methane was found. There were significant volumes of gas produced in duodenal and jejunal segments. Intestinal gas production was effectively inhibited or greatly reduced in animals pretreated with Neomycin Sulfate and sulfathalidine, Mexaform, and Vioform. Mexaform and Vioform effectively destroyed the anaerobic bacteria of the intestinal tract while the normal aerobic and coliform bacteria increased in total numbers indicating that the increased gas production from a bean homogenate was due to anaerobic intestinal flora.

- 60 INHIBITION AND AUGMENTATION OF PANCREATIC ELASTASE BY SERUM FRACTIONS FROM PREGNANT AND NORMAL HUMANS. (E.) Walford, R. L. (U. California Sch. Med., Los Angeles) and R. Sopher. Lab. Invest. 15(7):1248-1252, 1966.

John fractionation revealed that the inhibitor or inhibitors for the elastolytic and proteolytic effect of elastase (prepared from powdered pork pancreas) were not proportionately represented in different human serum protein moieties. The greatest total inhibitory activity for the elastolytic activity of pancreatic elastase resided in Fraction IV, while the greatest specific inhibitory activity was in Fraction VI which exhibited no appreciable inhibition of proteolysis. Subfractionation of Cohn fraction IV-1 of sera taken from 3 women in the last trimester of pregnancy revealed, in addition to the inhibitor (or inhibitors), material which selectively augmented the elastolytic activity of elastase. The subfraction was obtained by means of diethylaminoethyl cellulose chromatography.

- 61 5-HYDROXYTRYPTOPHAN DECARBOXYLASE ACTIVITY IN MONKEY AND RAT SMALL INTESTINE. (E.) Murali, D. K. (Christian Med. Coll. Hosp., Vellore, India) and A. N. Radhakrishnan. Biochem. Pharmacol. 15(6):735-740, 1966.

A comparison of the 5-hydroxytryptophan decarboxylase activity in the rat and the monkey showed the total activities in the jejunum and ileum to be more or less the same, while a relatively low activity was observed in the duodenum in both species. The low activities detected in the duodenum of rat intestine were comparatively lower than in monkey; even with low substrate levels the enzyme activity was easily detectable in the monkey duodenum and was distributed equally. The highest enzyme activity was found in the kidney of both the animals. The specific activity in the liver was of similar order, while the activity in the kidney and intestine of the monkey was about 6 times higher than those values in the rat. In the monkey the total activity in kidney or the intestine is about 4 times that in the liver, whereas in the rat, the activity in the liver is about 4 times that in the kidney and intestine.

- 62 THE REGULATION OF ALKALINE PHOSPHATASE ACTIVITY IN THE DUODENUM OF THE MOUSE FROM BIRTH TO MATURITY. (E.) Moog, F. (Washington U., St. Louis, Mo.). J. Exp. Zool. 161(3):353-367, 1966.

White mice (mostly Swiss strain) inj. s.c. with actinomycin D, cycloheximide, or puromycin dihydrochloride in saline or bicarbonate, and controls, inj. with vehicle only, were killed 50 hr. after the first inj.; in a few animals hydrocortisone was inj. before or after inj. of antibiotics. One cm of duodenum, distal to the pancreatic duct, was excised, weighed, frozen, and homogenized. In some instances jejunal samples were also obtained. The buffered enzyme-substrate (sodium betaglycerophosphate or disodium phenylphosphate) preparations were incubated for 5 min. The reaction products phenol and phosphorus, and protein conc. were determined. Other procedures used were adrenalectomy in some cases and mitotic counts of duodenal epithelium. Actinomycin D increased the alkaline phosphatase activity of the duodenum slightly in the first postnatal wk. but more markedly before the normal age of 20 days and later. The effect was not seen at 30 days but reappeared in adults. Puromycin had a powerful effect in enhancing the duodenal phosphatase activity after the first 9 postnatal days in all stages to the adult. Cycloheximide was also effective in young mice. In adrenalectomized mice the effect of actinomycin and puromycin was additive to phosphatase activity induced by hydrocortisone inj. Puromycin inhibited mitosis of duodenal epithelium in doses which elevated

GENERAL

phosphatase activity. It is pointed out that the phosphatase stimulating agents are inhibitors of protein synthesis and that phosphatase activation may be inhibited by a labile protein.

- 9563 EFFECT OF INTRAVENOUS PANCREOZYMIN ON AMINO ACID INCORPORATION IN VITRO BY PANCREATIC TISSUE. (E.) Webster, P. D. (Duke U. Med. Ctr., Durham, N. C.) and M. P. Tyor. Am. J. Physiol. 211(1):157-160, 1966.

When pancreatic tissue slices are obtained from pigeons 60, 90 or 120 min. after the i.v. admin. of 50 U of pancreozymin, an increase in the incorporation rate of L-phenylalanine- C^{14} into pancreatic tissue is observed. The increase is double or greater than that seen with saline-treated pigeons. The mean values of incorporation are the same for saline-treated and pancreozymin-treated pigeons when the pancreatic slices are obtained 15 or 30 min. after admin. of either saline or pancreozymin. The tissue slices were prepared and incubated for 60 min. in 10 ml. Krebs-Ringer phosphate soln. (pH 7.4) which contained 25 μ M of an amino acid mixture, 30 $m\mu$ M of the labeled substance and 100 μ M of glucose.

- 9564 HORMONAL REGULATION OF ISORENIN LEVELS IN THE SUBMANDIBULAR GLAND OF THE WHITE MOUSE AND LOCALIZATION OF THE ENZYME IN THE GLAND. (Ger.) Trautschold, I. (Inst. Clin. Chem., Dept. Surg., U. Munich, Germany), E. Werle, A. Schmal, and N. G. Hendrikoff. Hoppe-Seylers Zschr. Physiol. Chem. 344(4-6):232-243, 1966.

In male and female NMRI mice, the av. isorenin conc. in the submandibular glands was 4.0 and 1.0 U/g gland, resp. In males, orchiectomy caused a decrease in isorenin levels to female values. Females showed an insignificant decrease in isorenin values after oophorectomy. Testosterone (2.5 mg x 2/wk.) had no effect in males; in females it caused an increase in submandibular isorenin to male levels after 2 wk., accompanied by glandular hypertrophy, with normalization after several wk. Treatment with the anabolic preparation Testoviron (testosterone enanthate + testosterone phenylpropionate; 2.5, 25 or 250 μ g x 2/wk. s.c.) caused an increase in submandibular isorenin levels to male values at the 2 higher doses in female mice. Testosterone prevented the decrease in isorenin levels seen in orchiectomized mice; if the androgen was withdrawn, isorenin levels fell slowly. Hormone treatment beginning when isorenin values had reached the max. or minimum levels following oophorectomy or orchiectomy, resp., caused a rapid increase in isorenin levels to normal male values in both sexes. Thyroxin (0.02% in drinking water) had no effect on submandibular gland size or isorenin levels in males; females showed significant glandular hypertrophy and an increase in isorenin values to the male levels. Withdrawal of thyroxin resulted in normalization of isorenin levels, but the glandular hypertrophy persisted. Inhibition of thyroxin biosynthesis with 6-methyl-2-thiouracil (0.2% in drinking water) did not decrease isorenin levels. Cortisone and aldosterone (each 50 μ g/day for 6 wk. s.c.) had no effect in either sex; estradiol (given as Progynon Depot; 6 wk.) was without effect in females. Isoproterenol caused significant glandular hypertrophy in males (70 to 114 g) and females (40 to 66 g) within 2 wk., but isorenin levels fell to about 30% of normal. Since this catecholamine-induced hypertrophy involved only the acinar portion of the gland, compared to atrophy of the tubular portion, it is concluded that isorenin is synthesized in the striate bodies of the tubular portion. The effects of androgens and thyroxine in females and in orchiectomized males (which showed growth stimulation of this portion of the gland) lent further support to this conclusion.

- 9565 THE MICROFLORA OF THE RAT ALIMENTARY TRACT. II. QUANTITATIVE STUDY OF VARIOUS MICROBIAL GENERA PRESENT IN THE STOMACH AND INTESTINE OF ORDINARY RATS. NUMERICAL VARIATIONS BETWEEN INDIVIDUALS AND WITH AGE. (Fr.) Raibaud, P. (Cent. Res. Lab. Anim. Prod., Jouy-en-Josas, France), A. B. Dickinson, E. Sacquet, H. Charlier and G. Mocquot. Ann. Inst. Pasteur (Paris) 110(6):861-876, 1966.

Samples (105) of the digestive tract of 87 albino rats of 5, 10 and 15 days old were examined according to methods previously described. Lactobacillus count remains consistently high (10^9 /g of sample). Facultative anaerobic streptococci and Escherichia numbers vary greatly in the samples studied but appear to increase with age (from 10^6 to 10^{10}). Veillonella and Actinobacillus numbers increase with

NERAL

and the individual variations also diminish with age. Micrococcaceae levels/g fresh sample were usually below 10^2 and higher than 10^4 , especially in 15-day-old rats. Escherichia numbers (expressed as number of bacteria/g of fresh sample, 10^6) are greatly reduced in rats after weaning both in the stomach (7.0 to 3.4) and in the intestine (8.1 to 5.7). Viable bacteria increase between the stomach and cecum of rats both before and after weaning. Increases of Lactobacillus, Streptococcus, Actinobacillus and Veillonella were also observed. Increased numbers of the nonsporulating, Gram-strict anaerobes dominated the cecal flora.

- 66 THE SODIUM AND POTASSIUM ACTIVATED ATPase. II. COMPARATIVE STUDY OF INTESTINAL EPITHELIUM AND RED CELLS. (E.) Berg, G. G. (U. Rochester Sch. Med., New York) and J. Szekerczes. J. Cell Physiol. 67(3):487-500, 1966.

The Na- and K-activated ATPase (Na-K ATPase) found in the sedimentable fractions of intestinal epithelium of rats differed from that of other tissues in the following properties: substrate specificity, kinetics of activation by magnesium, selectivity for activating divalent cations and sensitivity to inhibition by zinc. Guanosine triphosphate (GTP) was hydrolyzed 25-50% as well as adenosine triphosphate by the Na-K ATPase of rat intestinal epithelium. The latter substance was active only in the presence of divalent cations with the following specificity: Mg^{++} 100%, Mn^{++} 50% and Ca^{++} 10%; while a second divalent cation caused inhibition, as did ouabain. The Na-K ATPase of intestinal epithelium was activated by sucrose extraction and denatured during cytolysis at room temperature. Residual ATPase from intestinal epithelium was a zinc-activated nucleoside polyphosphate phosphohydrolase which showed little preference for ATP over GTP or adenosine diphosphate and did not hydrolyze a monophosphate ester.

- 67 AUTOMATED DETERMINATIONS OF THYROID AND GASTRIC COMPLEMENT-FIXING ANTIBODY: COMPARISON WITH THE FLUORESCENT ANTIBODY AND MANUAL COMPLEMENT-FIXATION METHODS. (E.) Irvine, W. J. (Royal Infirmary, Edinburgh, Scotland). Clin. Exp. Immunol. 1(3):341-354, 1966.

- 68 MECHANISM OF ACTION OF BOVINE PANCREATIC RIBONUCLEASE. (E.) Deavin, A. (Univ. College, London), A. P. Mathias and B. R. Rabin. Nature (London) 211(5046):252-255, 1966.

- 69 POSTIRRADIATION CHANGES IN THE DISTRIBUTION OF PETHIDINE ADMINISTERED INTO THE GASTROINTESTINAL TRACT. (Cz.) Kvetina, J. (Charles U., Hradec Králové, Czechoslovakia). Sborn. Ved. Prac. Lek. Fak. Karlov Univ. 9(3):363-368, 1966.

- 70 UREA AND VOLATILE BASE IN THE CAECA AND COLON OF THE DOMESTIC FOWL: THE PROBLEM OF THEIR ORIGIN. (E.) Bell, D. J. (Poultry Res. Ctr., Edinburgh, Scotland) and T. P. Bird. Comp. Biochem. Physiol. 18(4):735-744, 1966.

- 9583 THE TRANSPORT OF BILIRUBIN IN THE CIRCULATING BLOOD AND ITS PATHOGENETIC IMPORTANCE. (E.) Bennhold, H. (U. Tubingen, Germany). Acta Med. Scand. 179(Suppl. 445):222-234, 1966.

- 84 INNervation OF THE SMOOTH MUSCLE OF THE INNER ANAL SPHINCTER. (Fr.)
 Alamowitch, C. (U. Paris Sch. Med., Sorbonne), J. P. Gubler and J. Roujeau.
Arch. Anat. Path. (Paris) 14(1):28, 1966.

One hundred rectums (derived from 48 fetuses, 21 stillbirths at term, 16 infants dead from various diseases, and 15 adults deceased from different medical and surgical causes) were excised, split longitudinally into 2 or 3 segments and prepared for sectioning through the region of the inner anal sphincter. The serial sections after staining were examined for neural structures. The innervation is represented by a plexus and nerve fibers, situated on the outer aspect of the sphincter of smooth muscle, a continuation of Auerbach's plexus of the rectal wall. Ganglion cells were found in only a relatively limited number of cases which increased with increasing age. Ganglion cells were found in only 25% of the total number of cases, in 15% of the earliest age group and in 50% of the adults. It is difficult to recognize the ganglion cells in the fetus where they are confused with other cells, especially the sheath cells of Schwann. The nerve net is situated most usually on the outer aspect between the inner smooth muscle sphincter and the striated muscle sphincter with the nerve fiber endings in contiguity with smooth muscle cells. Because of the variable number of ganglion cells in the plexus it is not possible to draw any definite conclusions regarding the relationship of pathologic states to the absence of ganglionic cells.

- 85 EFFECT OF ADRENAL STIMULATION ON HISTAMINE IN THE RAT STOMACH. (E.)
 Glick, D. (Stanford U. Sch. Med., Palo Alto, Cal.), D. Von Redlich, S. Levine and L. Jones. Gastroenterology 51(1):18-23, 1966.
- Male albino rats were kept under strictly controlled conditions of temperature ($26 \pm 1^\circ\text{C}$) and of light (12 hr./day). ACTH in physiologic saline was inj. i.p. in the acute experiments and ACTH in gel in the 12-day treatment tests. For fasting and for electric shock experiments, the rats were individually housed in wooden cages equipped with shocking grids at the food end of the cage. Shocking occurred when the food was approached 23 out of each 24 hr. At sacrifice mucosa of the greater curvature of the stomach was cleaned of food particles and stored at -20°C . For histamine (H) analysis the mucosa was stripped off, weighed, homogenized in perchloric acid, centrifuged, the supernatant saved; the homogenate was resuspended and again centrifuged. The supernatants were combined for fluorometric determination of H. The corticosterone in plasma was also determined fluorometrically. Adrenal stimulation in rats, indicated by elevated levels of plasma corticosterone, from fasting alone or with repeated electric shocks applied in 23 out of 24 hr. for 12 days caused significant reduction of conc. in the gastric mucosa. The effect of fasting was not enhanced when combined with shock and fasting alone or combined with shock resulted in ulcers in the forestomach and in the body of the stomach. Inj. of ACTH daily or the gel preparation alone caused a more pronounced decrease in H. No greater effect ensued when ACTH inj. was accompanied by fasting. Fasting appeared to increase the effect of the gel treatment. Single inj. of ACTH also lowered the H conc.

- 86 ELECTRON MICROSCOPIC EXAMINATION OF THE DEDIFFERENTIATED CELLS OF THE INTESTINAL EPITHELIUM. (E.) Tokin, I. B. (State U., Leningrad, USSR).
Acta Biol. Acad. Sci. Hung. 17(1):1-12, 1966.
- During the course of dedifferentiation of albino rat intestinal epithelial cells at the time of post-traumatic regeneration, the greatest electron microscopic changes take place in the structure of the ergastoplasm: the cylindrical elements are transformed into the vesicular type. Simultaneously, a considerable amount of free ribosomes appeared in the cytoplasm along with a great amount of lipoid inclusions. The trauma was brought about by mechanical strangulation which resulted in uniform and steady pressing down of the intestine. In addition, the Golgi complex became simplified to some extent and decreased in dimensions, while mitochondria of the dedifferentiated cells shortened and their dense bodies disappeared. Disregarding the significant changes in the shape and ultrastructure of the cells during regeneration, the connection between the dedifferentiated cells does not weaken. These

CELLULAR STRUCTURE AND MORPHOLOGY

changes seen in dedifferentiated cells allow many comparisons between malignant and 'embryonal' cells. Yet there are certain features as the characteristic structure of the cell membrane which are specific to cell dedifferentiation.

- 9587 CONTRIBUTION TO THE STUDY OF ARTERIAL VASCULARIZATION OF THE TERMINAL PART OF THE ILEUM. (Fr.) Cabanie, H. (U. Bordeaux Sch. Med., France) and M. Sentenac. C. R. Assn. Anat. (131):253-258, 1966.

In a series of 100 autopsies, it was found that the 3 generally accepted morphologic types of terminal distribution of the superior mesenteric artery were only generalized schemas, subject to innumerable intermediate and transitional forms. A morphologic type approaching the classical descriptions was encountered in only 28% of the subjects. Although the location of the trunk was relatively fixed, its termination might be found close to, or at a considerable distance from, the small intestine and at least 3 additional branches beyond and above the termination of the trunk, anastomosing a few cm from the mesenteric edge of the small intestine, were found in 60%. The ileocecal artery also showed a relatively fixed position, leading toward the ileocecal angle, but the number and position of branches within the angle formed by the mesenteric and ileocecal axes was extremely variable, frequently showing numerous arteries superposed above one another to form a sort of delta.

- 9588 SUBMICROSCOPIC STRUCTURE OF GALLBLADDER EPITHELIUM AND ITS REGENERATION. SECOND COMMUNICATION: CHICKEN AND VARIOUS MAMMALS. (Ger.) Bader, G. (Path. Inst., U. Jena, Germany). Zschr. Mikr. Anat. Forsch. 74(3): 303-320, 1966.

Electron microscopic studies of gallbladder epithelium derived from chickens, white mice, guinea pigs, rabbits, frogs, cats and dogs confirmed the writers' previous observations that microvilli were largely or entirely absent in regenerating cells which did not yet take part in resorption; as were plasma vesicles, both in the regenerating cells and in fully developed cells lying next to them. In chickens, the gallbladder epithelium appeared to be characterized by considerable secretory activity, with mucinous vessels increasing as sections were increasingly distant from the Golgi fields, culminating in a complete mucosal covering of apical cell sections. A similar phenomenon was observed in the other animals studied. In frogs, chickens and mammals alike, epithelial regeneration began with rod-shaped cells and followed a course similar to that which has been reported previously for fish.

- 9589 FIRST QUANTITATIVE DATA ON THE PARTICIPATION OF ENTEROCHROMAFFIN CELLS IN THE STRUCTURE OF RAT INTESTINE. (It.) Pedferri, G. (U. Pavia, Italy). Arch. Ital. Anat. Embriol. 71(1):35-48, 1966.

The number of enterochromaffin cells and fragments was determined microscopically in transverse sections of duodenal specimens obtained from 4 adult rats. From this data, the whole area occupied by the enterochromaffin cells was calculated. The area present in the peritoneal, muscular, connective, and epithelial portions of the duodenum was 4.5%, 8.0%, 37.3%, and 50.1%, resp. The enterochromaffin area comprised 0.210% of the total epithelial tissue and 0.105% of the total intestinal section. The significance of the above findings and the value of the technic used are discussed.

- 9590 ON THE DOUBLE INNERVATION OF THE PAROTID GLAND. AN EXPERIMENTAL STUDY. (E.) Genis-Galvez, J. M. (U. Salamanca, Spain), L. S. Gutierrez and M. M. Lopez. Acta Anat. (Basel) 63(3):398-403, 1966.

Two types of operations were made on the autonomic nervous system in order to determine the innervation of the secretory cells of the parotid gland. Unilateral postganglionic parasympathectomy was carried out in 1 group of cats by removing a 6-mm section of the auriculo-temporal nerve. Unilateral sympathectomy by extirpation of the superior cervical ganglion was accomplished in another group of cats. In all cases a bioptic study of the removed neural structures was made. In both series of cats the parotid glands of both sides were removed at intervals from 2-12 days and more. The gland of the unoperated side was used as a control.

CELLULAR STRUCTURE AND MORPHOLOGY

cial sections were stained with the Bielschowsky-Gros silver impregnation method and also Champy's osmium-zinc-iodine method. The histologic results indicate that the parasympathetic supplies the preponderance of fibers to the secretory cells. Sympathetic fibers terminate chiefly in the walls of the blood vessels and upon the cells of the gland cells.

- 91 MICROSCOPIC STRUCTURE OF BILE CANALICULI AFTER SUBTOTAL HEPATECTOMY.
(Ger.) Bartók, I. (U. Szeged, Hungary) and S. Virágh. Acta Morph.
Acad. Sci. Hung. 14(2):153-164, 1966.

The middle and left liver lobes were removed from adult male albino rats; subsequently, they received for 48 hr. 5.0 ml of 20% dextrose soln. 3 times daily, followed by standard diet up to day of sacrifice. At intervals from 20 days after surgery, 2 rats each were killed, liver tissue immediately fixed in 1% OsO₄ (in Palade buffer), and after alcohol dehydration, embedded in butyl-methyl-methacrylate. Two to 10 days after subtotal hepatectomy the number and diameter of bile canaliculi were seen to be increased; intracellular invaginations were seen in the bile capillaries, and changes in the shape and number of microvilli. These changes are illustrated in micrographs at 30,500 magnification, usually around and along the zonula occludens. Hypertrophy of Golgi apparatus and a differentiation as to color shade into "light" and "dark" of the liver cells could be observed simultaneously. The structural changes seen in the canaliculi gradually disappeared as the liver parenchyma regenerated. A relationship between enzyme activity (alkaline phosphatase and ATPase) of the regenerating liver, appearance and rate of the above described structural changes suggests that the latter may be expressions of increased activity of the surviving cells in order to accelerate regeneration.

- 92 STUDIES IN VIVO OF THE ILEOCAECO-COLIC SPHINCTER IN THE CAT AND DOG.
(E.) Jarrett, R. J. (Guy's Hosp., London) and J. C. Gazet. Gut 7(3):
271-275, 1966.

Food pressure was recorded from the right femoral artery, drugs were inj. via a cannula into the left femoral artery over the origin of the superior mesenteric artery. The vagi and the sympathetic (splanchnic) nerves were isolated. Ten cm from the ileo-cecal junction a 5-cm diameter tube was inserted abutting against the sphincter. The proximal ileum was ligated, preventing backflow, and a cecostomy performed (tube inserted). Normal saline or Tyrode soln. (30 drops/min.) was run into the ileum, and increase of pressure of 1 cm water/500 seconds. Effects in vivo of drugs on the sphincter correlated with the results in vitro, i.e. 25-50 µg of norepinephrine, norepinephrine, and acetylcholine stimulated and isoprenaline relaxed. The drug effects were consistent in 10 dogs and 10 cats; there was no correlation between effects on the sphincter and effects on blood pressure. Stimulation of the splanchnic nerves contracted the sphincter and increased blood pressure proportional to frequency of stimulating current. The response to distal vagal stimulation varied between animals and in the same animal. On the basis that β -receptors have been demonstrated in the sphincter, which when stimulated relax the muscle, it is suggested that the vagus contains adrenergic nerves which supply these receptors.

- 93 INTESTINAL DIPEPTIDASES. IV. STUDIES ON THE RELEASE AND SUBCELLULAR DISTRIBUTION OF INTESTINAL DIPEPTIDASES OF THE MUCOSA CELLS OF THE PIG.
(E.) Josefsson, L. (U. Lund, Sweden) and H. Sjöström. Acta Physiol.
Scand. 67(1):27-33, 1966.

Mucosa was prepared by scraping from sections of small intestine of adult pigs received immediately after slaughter. Dipeptidase activities were determined by spectrophotometric methods. Release of dipeptidase into 0.25 M sucrose soln. was compared for mucosal scrapings, intact pieces of intestine, and homogenized mucosa. It was found that dipeptidases were released very quickly (10-25 seconds) when mucosal scrapings were placed in aqueous soln. Release from intact intestine was lower, but equal yields were obtained. Both scrapings and intact pieces of intestine gave superior yields compared to homogenized mucosa. Histologic examination revealed that cell membranes remained intact during release. No conclusion could be made about intracellular location of the enzymes because of their rapid release to the solvent.

CELLULAR STRUCTURE AND MORPHOLOGY

PRESERVATION OF THE SECRETORY GRANULES OF RAT PAROTID GLAND FOR ELECTRON MICROSCOPY. (E.) Robinovitch, M. R. (U. Washington, Seattle), L. M. Sreebny and E. A. Smuckler. Exp. Cell Res. 42(3):634-639, 1966.

Parotid gland tissues of rats were immediately removed and placed in fixative solution of 1% osmium tetroxide in 1) Caulfield's buffer, 2) s-collidine, 3) 0.2 M phosphate, 4) 0.075 M cacodylate. Other tissues were fixed in 6.25% glutaraldehyde in 0.075 M cacodylate buffer, washed in 0.2 M sucrose in 0.1 M cacodylate buffer and post-fixed in 1% osmium tetroxide in Caulfield's buffer. After fixation tissues were prepared and sectioned, double stained with uranyl acetate and lead hydroxide and observed in an electron microscope. Sections were also cut, stained with azure II-methylene blue and studied by light microscopy. Acinar secretory granules stained with azure II-methylene blue when studied by light microscopy appear round and heavily stained and homogeneously blue when fixed in glutaraldehyde; when fixed in osmium tetroxide the granules appear round and lightly stained. In electron microscopy osmium tetroxide-fixed acini are irregular in shape, have incomplete membranes and contain a flocculent low electron dense material regardless of what buffer is used. Glutaraldehyde-fixed granules are round to oval, consistently denser than ground cytoplasm and have complete membranes. The granules are homogeneous and electron dense. Two types of granules are discriminable, one in the Golgi regions, the other in cytoplasm. In rats pretreated with pilocarpine the number of denser granules (cytoplasm) is decreased. It is suggested that osmium tetroxide without prior fixation with aldehydes brings about the solubilization of the contents of the secretory granules.

9595

MAST CELLS IN RAT GASTROINTESTINAL MUCOSA. 4. MONOAMINE STORING CAPACITY. (E.) Enerbäck, L. (U. Gothenburg, Sweden). Acta Path. Microbiol. Scand. 67(3):365-379, 1966.

The effects of reserpine, L-dopa, DL-hydroxytryptamine phosphate (DL-5-HTP), dopamine, 5-hydroxytryptamine (5-HT), semicarbazide and isoniazid, on the distribution and monoamine content of mast cells were studied in dorsal skin, thymus, esophagus, forestomach, glandular stomach, duodenum and small intestine of rats. Cellular localization of monoamines was accomplished by the method of Falck and Owman using the fluorescence microscope after treatment with formaldehyde vapor. The metachromatic component of the mast cell granules was demonstrated by staining with toluidine blue at pH 4 or 0.5, astrablue at pH 0.3 and aldehyde-fuchsin in 60% alcohol. The experiments were done so control tissues and treated tissues were handled together throughout the histochemical procedure. The sections were judged under blind conditions for the degree of fluorescence present. Mast cells in the gastrointestinal mucosa did not show the yellow fluorescence after formaldehyde treatment typical of 5-HT-containing structures. The mast cells showed a weak greenish fluorescence which was considered evidence that they contained a monoamine. Reserpine (25 mg/kg i.p.) abolished or decreased this fluorescence 24 hr. after inj. in duodenal sections. Two doses were required to reduce the fluorescence in mast cells of the tongue. L-dopa increased the fluorescence 2 hr. after inj. of 40 mg/kg i.p.; 5-HTP increased fluorescence but was yellow rather than green as following L-dopa. Neither 5-HT or dopamine affected fluorescence. The increase seen following inj. of L-dopa could be blocked by admin. of reserpine 24 hr. before. Neither isoniazid or semicarbazide blocked the L-dopa effect. It is concluded that the gastrointestinal mucosa of the rat contains at least 3 cell types: enterochromaffin cells showing strong yellow fluorescence (after formaldehyde) probably due to 5-HT, a type of cell abundant in the intestine showing greenish fluorescence (blocked by reserpine) probably due to a monoamine, specific enterochromaffin-like cells normally non-fluorescent that take up dopa and 5-HTP and decarboxylate them.

9596

INFLUENCE OF DIET AND BACTERIA ON SMALL INTESTINAL MORPHOLOGY, WITH SPECIAL REFERENCE TO EARLY WEANING AND Escherichia coli. STUDIES WITH GERM-FREE AND GNOTOBIOTIC PIGS. (E.) Kenworthy, R. (Unilever Res. Lab., Sharnbrook, Bedford, England) and W. D. Allen. J. Comp. Path. 76(3):291-296, 1966.

Using a coagulase-negative staphylococcus, pathogenic and non-pathogenic strains of Escherichia coli and total flora as contaminants with germ-free pigs, it was

CELLULAR STRUCTURE AND MORPHOLOGY

monstrated that the particular bacteria affects intestinal mucosal morphology. In the monocontaminated animal, villi were long, slender and classically finger-shaped with great conformity in villus height and width, and crypt depth. With the multicontaminant, this remarkable uniformity was not maintained, while mucosal damage was extensive in those animals placed in a normal pig environment. In the latter situation, villi were stunted and leaf shapes were observed with evidence of clubbing and fusion of the villi. A characteristic feature of limited contamination was the tall columnar nature and basally situated nucleus of the epithelial cells on the villi; whereas in the multi-contaminated animals, the cells were cuboidal with a centrally located nucleus. The crypt depth was increased and the villus height reduced in the multicontaminants. In all cases, a linear relationship was seen between the mitotic index and the crypt villus ratio.

- 97 CELL POPULATION KINETICS IN THE INTESTINE OF CONTINUOUSLY IRRADIATED MICE, USING DOUBLE-LABELLING AUTORADIOGRAPHY. (E.) Wimber, D. E. (Royal Cancer Hosp., Sutton, Surrey, England) and L. F. Lamerton. Radiat. Res. 28(3):694-700, 1966.

major changes occurred in the duration of DNA synthesis or in the mitotic time of the ileal epithelial cells of mice (male: strong A type) which had been subjected to continuous irradiation for 5 days at 50, 84 or 176 rads/day. The duration of the DNA synthesis in control animals was 6.4-0.4 hr. and the time for mitosis was 0.4 hr. The number of cells per crypt was also similar in the control and irradiated mice, yet a large amount of cell death and loss was evident in the irradiated animals at every dose level examined. This would indicate that the latter effect is compensated by an increased cell production: either by shortening the G₂ periods or by increasing the number of proliferating cells or both. These results are not the same as those obtained when rats were irradiated in the same way. A C¹⁴, H³-TdR double-labeling method was used after irradiation to follow the cell population changes.

- 98 THE VESSELS OF THE DUCTUS CHOLEDOCHUS. (Ger.) Ranga, V. (Inst. Med. Pharm., U. Bucharest, Rumania) and P. Andronescu. Anat. Anz. 118(5):516-521, 1966.

Angiographic studies (70% Iodopac) on fresh adult and newborn cadavers are presented and microphotographs of the vascular systems of the hepatic and common ducts are described. The latter were obtained by ligating the proper hepatic arteries at the liver hilus, and both the right gastroepiploic and gastric arteries, then injecting India ink mixed with gelatin into the common hepatic artery. A capillary net was visualized below the mucosa, somewhat similar to that of the gallbladder, but without the radial arrangement seen in the latter. The loops of this submucosal plexus are perpendicular to the longitudinal axis of the common duct, especially in its lower half; the net is richly arteriolized. The efferent veins form a second vascular stratum below the capillary net but contrary to literature data, there seems to be no arteriolar plexus below the capillary layer. Transition into the portal veins can be seen as a sudden change of caliber. The efferent veins are richly anastomosed; the larger ones accompany the arteries; these form the superficial vascular layer. The presence of arterial anastomoses is also evident; some are of the mesenteric type, especially near the opening of the cystic duct. A number of anastomoses are available to insure positional and pressure adaptability (loops, spirals, double branches, etc). It appears that the difficulties arising from surgical intervention into the common duct are due not only to the superficial positioning of the arteries, but also to the unique, almost horizontal spread of the capillary network.

- 99 RECENT PRINCIPLES OF PHYSIOPATHOLOGY IN THE LYMPHATIC CIRCULATION OF THE LIVER. (It.) Zangrando, O. (U. Padua, Italy), G. Segato, G. Frazzini, G. Rosa and G. Mantovani-Orsetti. Minerva Chir. 21(7):255-264, 1966.

Studies on hepatic (hilar) and thoracic duct lymph flow and composition in dogs before and after ligation of the common bile duct showed that in both locations lymph flow decreases slightly in the first hr. after ligation, then increases deeply to a max. (+ 87%) at 4 hr., after which it falls toward the initial level.

CELLULAR STRUCTURE AND MORPHOLOGY

A progressive increase (for at least 5 hr.) in both direct (hepatic and thoracic lymph) and total (hepatic lymph) bilirubin was found after ligation. Serum bilirubin values remained essentially unchanged. Total bilirubin values were always higher in hepatic lymph than in either serum or thoracic lymph; after hr. 3, thoracic lymph bilirubin also rose above the serum level. The conc. of bile acids in all 3 fluids rose to a peak at 2 1/2 hr., then fell until at 4 1/2 hr. it again began to rise; hepatic lymph values were always greater than those of thoracic lymph, where during the first increase hepatic lymph values were greater than serum values, but the reverse was true during the second increase. The authors believe that during the first hr. after ligation, the liver is in a state of "functional stupor," after which it resumes functioning, and lymph flow is increased as it is used to eliminate bilirubin and bile acids; the latter, however, are absorbed by the lymphatic circulation only in the first 1-3 hr., after which venous absorption also occurs. The decrease in lymph flow after 4 hr. is unexplained except as a result of superimposed stress in the experimental animals.

- 9600 HYPOTHERMIA OF ORGANS. ULTRASTRUCTURAL PROJECTIONS IN DEEP LOCAL HYPOTHERMIA OF THE STOMACH. PRELIMINARY NOTE. (It.) Martines, G. (U. Ferrara, Italy), G. Motta and G. F. Musacci. Minerva Chir. 21(2):63-66, 1966.
- Specimens of dog stomach wall taken at varying distances from areas subjected to deep local hypothermia were fixed, embedded and the most significant levels chosen from thick serial sections by examination with the phase contrast microscope. Very thin sections were then cut with a Leitz ultramicrotome, spread on Formvar membrane and stained with uranyl acetate and examined with the electron microscope. Findings include (1) in submucosal blood vessels: nuclear changes with margination of chromatin; rarified cytoplasm with lack of structures; vacuolation of mitochondria; interruption of an endothelial cell membrane; and aggregation of material, including prismatic bodies in a capillary lumen; (2) in the secretory cells of the fundus: a pyknotic nucleus with margination of chromatin and indentation of its membrane; vaguely defined Golgi apparatus; and sparse, degenerate mitochondria, including one with a horseshoe shape and increased density of its contents.

ABSORPTION

7 ROLE OF LONG EXTRACELLULAR CHANNELS IN FLUID TRANSPORT ACROSS EPITHELIA.

(E.) Diamond, J. M. (Harvard Med. Sch., Boston, Mass.) and J. McD.

Tormey. Nature (London) 210(5038):817-820, 1966.

er transport in isolated, cannulated rabbit gallbladders was measured by means of gravimetric method previously described by the authors, and sections were examined by phase contrast and electron microscopes. The lateral cell surface of the epithelial cell is greatly increased by cytoplasmic projections into the lateral extracellular space, which is sealed off from the luminal contents by a continuous system of terminal bars joining the cells at their luminal borders. The lateral extracellular spaces were found to be dilated under conditions of measured maximum water transport, and closed or nearly closed when water transport had been stopped by one of 4 methods: low temperature, ouabain, isotonic luminal sucrose, and hypertonic luminal soln. Because measured changes in cell size and back pressure did not account for the dilatation of the lateral spaces, the most probable explanation is that the water flows from the cell by way of the lateral space (the luminal end of which is hypertonic due to acute transport of NaCl out of the cell) and out through the basement membrane, with dilution of the salt to an isotonic concentration during the passage. It is suggested that similar structure in other epithelia may function in the same way.

8 ACTIVE TRANSPORT OF D-MANNOSE IN THE SMALL INTESTINE. (E.) Csáky, T. Z.

(U. Kentucky Coll. Med., Lexington) and P. M. Ho. Life Sci. 5(11):1025-

1030, 1966.

ng isolated small intestine of frogs (Rana pipiens) incubated with D-mannose for 1 hr. at 30°C, an active transport system for this sugar is described which is dependent on sodium and is inhibited by low conc. of digitalis. Moreover, the capacity of the "mannose pump" of this active transport system is low; a sugar concentration between 5-12 mM inactivates it. This low capacity feature is probably why an intestinal D-mannose pump has not previously been reported and why D-mannose was classified as a sugar which is not actively transported. These experiments support the concept that there is no specific structural requirement for active transport and that essentially all sugars which enter the intestinal epithelial cell by carrier-mediation are subject to pumping, but the capacity of the pumps varies widely for different sugars.

9 THE IRON TOLERANCE TEST. MEASUREMENT OF ABSORPTION AND UTILIZATION OF A

THERAPEUTIC DOSE OF IRON. (E.) Wiltink, W. F. (Dijkzigt Hosp., Rotterdam,

The Netherlands), H. J. Ybema, B. Leijnse and J. Gerbrandy. Clin.Chim. Acta 13(6):701-707, 1966.

Measurements made after the oral admin. to 36 patients of about 250 mg of iron, whether the ferrous or ferric salt mixed with 5 μ C Fe⁵⁹, showed a significant correlation between iron utilization by the RBC and the plasma iron conc. (iron tolerance curve). In contrast, no correlation existed between iron absorption and the iron tolerance curve. The hemoglobin level correlated with neither the iron tolerance test, the absorption nor utilization. It did correlate with the fasting plasma iron and negatively with latent iron-binding capacity. The highest plasma iron level, which was followed for 7 hr., occurred usually 2-3 hr. after iron ingestion. The urine radioactivity always amounted to less than 2.3%. These data suggest that a temporary iron pool accumulates between the intestinal lumen and the inferior vena cava, probably in the intestinal wall, and release from this pool depends on the demand by the bone marrow.

10 IN VIVO INTESTINAL ABSORPTION OF L-ALANINE IN IRRADIATED RABBITS. (E.)

Mehran, A. R. (Laval U., Quebec, Canada) and R. Blais. J. Nutr. 89(2):

235-240, 1966.

portal vein and the posterior vena cava of anesthetized, fasted rabbits were cannulated. Two ml water containing 20 μ C labeled L-alanine-C¹⁴ were inj. into the duodenum 7 cm from the pylorus. Blood samples (0.5 ml) were taken at intervals through the catheters and prepared for counting. Hematocrit values were determined

ABSORPTION

during the experiment as were respiratory rate and electrocardiograms. Experimental animals were tested 4 days after irradiation (300 r or 600 r). Histological examination showed slight effects on absorbing cells of the intestine. Activity curve showed a rapid rise and fall in blood drawn from the portal vein under conditions of both radiation and control. Absorption was nearly complete in 50 min. No significant differences in amount or pattern of absorption of alanine was found in any of the groups. Activity in femoral blood, believed to reflect the metabolism of alanine, showed a slower increase in radiated rabbits. It is concluded that radiation had no effects on absorption but may affect the metabolism of alanine.

- 9611 MECHANISM OF ACTION OF DEFEROXAMINUM ON IRON ABSORPTION. (E.) Balcerzak S. P. (U. Pittsburgh, Pa.), W. N. Jensen and S. Pollack. *Scand. J. Haemat.* 3(3):205-212, 1966.

Normal volunteers and hematologically normal patients without gastrointestinal disease were given combinations of Fe^{59} , Fe^{55} , and deferoxaminum (DFO) to study absorption. Counting was done in a liquid scintillation counter using Dern and Hart's method, when both Fe^{59} and Fe^{55} were present. Fe^{59} alone was measured in a crystal scintillation counter. Ionic iron was given as ferrous sulfate, organic iron as rabbit hemoglobin. When Fe^{59} and Fe^{55} drinks were taken on alternate days DFO was found to impair either the absorption or incorporation of iron into RBC or both. DFO was effective whether the iron and DFO were mixed in a flask, in the stomach or in the intestine (duodenal infusion). The block of iron entry into plasma was found to be incomplete, even when excess DFO was present. Some absorbed iron was excreted in the urine with DFO; whether DFO combined with this absorbed iron before or after transfer to plasma could not be determined. DFO (i.v.) chelated ionic iron in the presence of transferrin, once iron was bound; however, DFO could not remove it. It is concluded that hemoglobin-bound iron absorption is a different mechanism than ionic iron. It is suggested that DFO would not be of benefit to patients having iron overload.

- 9612 ABSORPTION AND STORAGE OF RETRO-VITAMIN A ACETATE. (E.) Murray, T. K. (Dept. Nat. Health Welfare, Tunney's Pasture, Ottawa, Canada) and P. Erdody. *Biochim. Biophys. Acta* 124(1):190-191, 1966.

Three mg retro-vitamin A acetate was admin. p.o. to 45 vitamin A-deficient male rats. Groups of 15 were killed at 5, 24, and 48 hr. The small intestine and its contents were assayed separately. Stomach and cecum were assayed with their contents. Proportions of vitamin A and retro-vitamin A were measured by the method of Varma and Murray. Total vitamin A was estimated by the antimony trichloride reaction. Thirty per cent could be accounted for 5 hr. after admin. mostly in the gastrointestinal tract. After 24 hr. only the liver contained either vitamin A or retro-vitamin A. Retro-vitamin A was the predominant form reaching the liver; conversion to vitamin A was approx. complete at 72 hr. Evidence indicated that retro-vitamin A acetate was directly absorbed in the intestinal tract and little hydrolysis occurred; this resistance to hydrolysis was also demonstrated in vitro. It was concluded that the studies illustrated the unique metabolism of retro-vitamin A which is absorbed, transported, stored, and converted to vitamin A without hydrolysis and re-esterification.

- 9613 INTERFERENCE BETWEEN LEUCINE, ISOLEUCINE AND VALINE DURING INTESTINAL ABSORPTION. (E.) Szmecman, S. (Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel) and K. Guggenheim. *Biochem. J.* 100(1):7-11, 1966.

A test meal of 5 g starch in 100 ml aqueous soln. of L-leucine and/or L-isoleucine and/or L-valine (5 ml/100 g) was admin. by stomach tube to 48-hr. starved 70-wk.-old rats. Samples of portal plasma and intestinal contents were obtained at 10, 30, and 60 min. Samples were assayed for the 3 amino acids micro-biologically. In vitro studies were done with everted rat intestinal sacs (14 cm). Various combinations of the amino acids were dissolved in Krebs-Ringer soln. containing 0.3% glucose, and placed in the sacs 1.0 ml and in the bath 25 ml. Amino acids were assayed microbiologically after 3 hr. incubation. Interference with the absorption of leucine by isoleucine or valine and of the absorption of isoleucine and valine by leucine was demonstrated both in vivo and in vitro. In vivo inhibition of absorption was partly overcome by 30-60 min., probably by absorption of the

ORPTION

erfering amino acid. Active absorption of amino acids was rapid at low conc. depressed at higher conc. It is suggested that the high conc. depression might be due to unspecific overloading of a carrier system as well as by specific antagonism.

- 4 EFFECT OF A LOW IRON DIET ON IRON ABSORPTION. (E.) Rush, B. (Washington U. Sch. Med., St. Louis, Mo.), M. A. Figallo and E. B. Brown. Am. J. Clin. Nutr. 19(2):132-136, 1966.

Fourteen medical students and laboratory staff were given an iron-poor liquid diet (5-2.9 mg iron/day) for 7 days and an iron-rich liquid diet (14-15 mg iron/day) for 7 days. The diets were otherwise nutritionally normal. Twelve subjects received the iron-poor diet first followed by the iron-rich diet and vice versa for other subjects. Iron absorption (measured by a fecal balance technique) was measured at the end of each 7-day period, 5 mg iron sulfate labeled with $10 \mu\text{C}$ Fe^{59} given orally, stool collection was carried out until radioactivity had disappeared. Serum iron and iron-binding capacity were determined. There were no significant differences in per cent radio-iron absorbed after either diet. Supplementary iron, 15 mg ferrous sulfate, in 3 subjects resulted in lower absorption than the iron-poor diet. It is concluded that the effects demonstrable in rats following iron deficiencies have no bearing on man and should be treated as separate phenomena.

- 5 INHIBITION OF PROTEIN SYNTHESIS: A MECHANISM FOR THE PRODUCTION OF IMPAIRED IRON ABSORPTION. (E.) Greenberger, N. J. (Ohio State U. Hosp., Columbus) and R. D. Ruppert. Science 153(3733):315-316, 1966.

Two groups of rats (controls, 2 wk. of low iron diet prior to study, i.m. inj. of 1 mg Imferon 2 wk. prior to study, 5 mg/kg i.p. of cycloheximide 3 hr. prior to study) were used to investigate intestinal iron transport. Sixteen to 20 cm of intestine was isolated by ligatures and an intraduodenal inj. of $\text{Fe}^{59}\text{SO}_4$ (50 μg) in.; 30 min. later the intestine was excised, washed, and the mucosa and contents counted. In controls there was 65% uptake (inj.-recovered in contents) and 56% transfer (uptake-Fe in mucosa) of the inj. dose. In low-iron diet rats increased mucosal uptake, 83%, and transfer, 56%, were observed. Imferon and cycloheximide decreased both, 52% and 16% and 29% and 12%, resp. In iron-deficient rats only 33% iron remained in mucosa after 30 min. compared to 42% for controls and 60% for iron-treated animals and 54% for cycloheximide rats. It was found that in cycloheximide rats the rate of iron absorption was slow, 23.5 $\mu\text{g}/60 \text{ min.}$, compared to 7.4 $\mu\text{g}/60 \text{ min.}$ for controls of a 50- μg dose; glucose was absorbed normally, and no histologic changes were noted. It is suggested that the interference in iron transport may be due to a deficiency of an unidentified carrier substance, which might be a protein, polypeptide or any specific amino acid which forms complexes with iron.

- 6 RECOVERY OF PANCREATIC EXOCRINE SECRETORY CAPACITY FOLLOWING PROLONGED DUCTAL OBSTRUCTION. BICARBONATE AND AMYLASE RESPONSE TO HORMONAL STIMULATION. (E.) Tiscornia, O. M. (Mt. Sinai Hosp., New York) and D. A. Dreiling. Ann. Surg. 164(2):267-270, 1966.

Pancreatic secretion, bicarbonate output, amylase secretion and mean bicarbonate and amylase conc. were determined for collected pancreatic secretions in 14 dogs following 5 U/kg secretin and pancreozymin, 4, 8, or 12 U/kg secretin or infusion of secretin and pancreozymin. The dogs were studied both before and after ligation and re-anastomosis (7-46 days) of the pancreatic duct and again 7 days after re-anastomosis. Collections were made by catheterization of the duct via a Thomas cannula. Biopsies were taken at surgery and at death. Serial pancreatograms and serum blood amylase determinations were done. Normal pancreatic architecture was restored in 8 of 12 dogs; 2 died. Secretion flow, bicarbonate output and amylase production was reduced for 8 wk. following re-anastomosis, but returned to normal levels. Recovery was observed following up to 46 days of obstruction. Ability to produce a conc. soln. of amylase was affected more than for bicarbonate secretion.

ABSORPTION

- 9617 ELECTRON-MICROSCOPE EVIDENCE FOR INTRAMICROVILLOUS FAT ABSORPTION BY THE SMALL INTESTINAL EPITHELIUM OF RATS. (E.) Shiner, M. (Central Middlesex Hosp., London). Gut 7(2):107-113, 1966.

Two starved rats (36 hr.) were anesthetized and their abdomens opened; in rat 1, 0 ml of 3% glutaraldehyde-cacodylate fixative pH 7.4 was injected into the lumen of the jejunum one min. before a ring of intestine was excised just beyond the duodeno-jejunal flexure. The second rat was treated similarly except that 0.5 ml linseed oil was inj. into the duodenum 5 min. preceding fixation of the jejunum. Excised tissues were fixed, embedded and sectioned, stained with uranyl acetate and lead citrate preparatory to electron microscopy. In the micrographs of rat 2 numerous dense droplets, 100-300 Å, were seen in the region of the microvilli and a few 500 Å droplets in the area of the terminal web. The 500 Å drops did not appear surrounded by membrane. Usually the droplets occurred within the double membrane of the microvilli, or attached to the inner of the 2 membranes. These findings and the speed at which they occurred were felt to indicate that fat droplets could enter through the membranes of the microvilli and be carried either along the membranes or in the interior of the microvillus to the main cell without the requirement of a pinocytic mechanism. How the droplets diffuse through the membrane is not presently known. It is suggested that entry of lipids by diffusion may not be the only mechanism of transport and that there may be a specific receptor mechanism at the cell membrane.

- 9618 EFFECT OF MAGNESIUM DEFICIENCY ON GASTROINTESTINAL TRANSFER OF CALCIUM. (E.) Kessner, D. M. (Yale U. Sch. Med., New Haven, Conn.) and F. H. Epstein. Proc. Soc. Exp. Biol. Med. 122(3):721-725, 1966.

The capacity of everted duodenal segments to transport Ca against a conc. gradient from mucosa to serosa is augmented 24-60% when the rat from which the duodenal segment is taken has been on a deficient diet. Despite the hypomagnesemia the Mg content of the intestine was unaltered. The addition of mg to a final conc. of 2 mEq/liter to the serosal and mucosal fluids did not reduce the elevated Ca serosa mucosa ratio. However, when the conc. of Mg bathing the sacs was increased to 200 mEq/liter, marked inhibition of Ca accumulation was noted. These effects of Mg bathing were noted in the controls as well as those with Mg depletion. Although a direct effect of Mg depletion on cellular transport mechanisms is not ruled out, the authors feel the results are consistent with a humoral influence, like that of parathyroid hormone.

- 9619 FUNCTIONAL COMPENSATION AFTER SMALL-BOWEL RESECTION IN MAN. DEMONSTRATION BY DIRECT MEASUREMENT. (E.) Dowling, R. H. (Postgrad Sch. Med., London W. 12) and C. C. Booth. Lancet 2(7455):146-147, 1966.

After small intestine resection, involving from 7 in. to 7 1/2 ft. in 8 patients, the capacity of the intestinal remnant to absorb glucose increased significantly. Intubation of a standard length of jejunum with a double lumen tube (after an overnight fast) allowed direct measurement of glucose absorption which averaged 60.9 mg/25 cm of jejunum/min. for the resection patients and 48.3 for the controls. In general, the more extensive the resection, the greater the glucose absorption. The patients ranged from 28-76 yr. of age and the time since the resection operation ranged from 2 mo.-40 yr.

- 9620 SECRETION AND ABSORPTION OF MESOBILIRUBINOGEN-H³ STUDIED BY AUTORADIOGRAPHY. (E.) Stumpf, W. E. (U. Chicago, Ill.) and R. Lester. Lab. Invest. 15(7):1156-1162, 1966.

Male rats anesthetized with ether were injected i.v. with 1.0 mg of mesobilirubino-gen-H³ dissolved in rat serum. At 30 seconds, 3, 8 and 30 min. the median lobe of the liver was excised, frozen and prepared for autoradiography. Intestinal absorption was studied by inj. of 0.5 mg of mesobilirubino-gen-H³ in 5 mm aqueous taurocholate into the jejunum of anesthetized rats. Tissue was excised at 40, 100 and 195 seconds (similar tissue was collected following i.v. admin.), frozen and prepared for autoradiography. Hepatocyte uptake of mesobilirubino-gen-H³ was rapid (30 seconds), no conc. of activity occurred in Kupffer cells. Heavy conc. of labeled compounds occurred in bile canaliculi and bile ducts. No evidence of

ORPTION

bsorption through the biliary epithelium was obtained. Extensive and rapid orption of mesobilirubinogen by the intestinal villi was observed.

1 PLASMA RADIOACTIVITY AFTER RADIOACTIVE VITAMIN B₁₂ GIVEN ORALLY. (E.) Coupland, W. W. Med. J. Aust. 1(24):1020-1023, 1966.

7-labelled vitamin B₁₂ is the ideal radioactive vitamin B₁₂ preparation for use studies of B₁₂ absorption due to its lower energy and longer half-life than 8-labelled vitamin B₁₂. Technics are presented. A comparison with the urinary retention method is also presented showing a direct correlation while exhibiting advantages or simplicity of method, rapidity, single sample collection, esthetic eal, and lack of necessity of patient cooperation. Plasma radioactivity after 1 Co57-labelled vitamin B₁₂ admin. is also an effective tool for the degree of am B₁₂ absorption in patients with renal failure, a condition which invali- es the urinary excretion method. A clear distinction is provided between these jects who can and those who cannot absorb vitamin B₁₂.

2 NORMAL AND PATHOLOGIC VARIATIONS OF CHYLOMICRONS DURING ARTIFICIALLY INDUCED HYPERLIPIDEMIA. (Fr.) Warter, J. (U. Hosp., Strasbourg, France), P. Métais, A. Bach and G. Berthier. Path. Biol. (Paris) 14(9-10): 546-553, 1966.

ulation of the increase of serum chylomicrons 1-10 hr. after ingestion of an lsion of equal parts of olive or peanut oil and water resulted in a sharply ing curve in normal subjects which peaked within 2-4 hr. after admin. and then lined somewhat less rapidly to reach pretreatment levels between hr. 10-13. ng patients with obstructive jaundice, 26 of 31 failed to show any increase of omicrons, presumably due to the absence of bile salts; 4 of 31 showed marked tening of the curve; 1/31 showed a normal curve. There was no discernible ationship between the response and the cause of obstruction. The incidence of ure to show any increase, flattened curves, delayed peaks and normal curves tabulated for other patient groups as follows: virus hepatitis = 2/21, 8/21, and 5/21, resp.; liver and gallbladder disorders (e.g., lithiasis, hepatic hosis, etc.) = 5/36, 8/36, 8/36 and 15/36, resp.; diabetes = 0/3, 0/3, 1/3, 2/3, resp.; gastric disorders = 0/18, 2/18, 10/18 and 6/18, resp.; pancreatic rders without jaundice = 6/35, 12/35, 17/35 and 0/35, resp.; enterocolitis in presence of sprue = 2/7, 1/7, 4/7 and 0/7, resp.; lymphatic leukemia and kin's disease = 3/7, 1/7, 3/7 and 0/7, resp.; other (cancerous and tuberculous) opathies = 0/2, 2/2, 0/2 and 0/2, resp. It is concluded that the test has nite diagnostic value in the presence of suspected anomalies of absorption, rmalities of intestinal mucosal function, or disorder of the lymphatic system in Hodgkin's disease).

RELATION OF VITAMIN A RESORPTION TO PROTEIN INTAKE. (Ger.) Rodel, W. (Nutrition Inst., Potsdam/Rehbrücke, Germany) and J. Pröll. Inst. Zschr. Vitaminforsch. 2(36):137-148, 1966.

adult male Wistar rats, feeding for 4 weeks of an isocaloric mixture containing 10 or 18% protein had no effect on vitamin A resorption from the gastro- stinal tract or on hepatic content of vitamin A after peroral doses of 18 or .U. per cm² of body surface. After 3 hr. resorption, the vitamin A content of intestinal tract and walls was significantly increased above normal, but vita- A esterase activity was diminished. It is believed that the latter phenomenon no effect on the capacity to utilize vitamin A.

EFFECTS OF SEVERAL DRUGS ON INTESTINAL BLOOD FLOW AND RESORPTION OF TRITIATED WATER FROM THE SMALL INTESTINE OF THE RAT. (Ger.) Winne, D. (Pharmacol. Inst., U. Tübingen, Germany). Naunyn Schmiedeberg. Arch. Exp. Path. 254(3):199-224, 1966.

rethane-anesthetized, adult Wistar rats, both the venous outflow of a jejunal and the absorption rate of tritiated water from the loop were decreased by of the tritiated water into the loop (as contrasted to perfusion through the n) and by i.v. infusion of 5-hydroxytryptamine creatinine-sulfate monohydrate g/min.), norepinephrine bitartrate (6 µg/min), and lysine-8-vasopressin

ABSORPTION

(20 mU/min.). Both were increased by i.v. infusion of histamine dichloride (50 μ g/min.) or i.v. inj. of 150 μ g atropine sulfate (hydrate). No effect was exerted by i.v. inj. of mersalyl (3 mg) or neostigmine bromide (15 μ g). It is concluded that the rate of absorption of tritiated water was directly proportional to the rate of intestinal blood flow, suggesting that the latter may be a primary factor in determining the rate of absorption of water soluble drugs.

- 9625 COMPARATIVE STUDIES OF VITAMIN RESORPTION. (Ger.) Gassmann, B. (Nutrition Inst., Potsdam/Rehbrücke, Germany), J. Prohl, H. Schmandke and W. Rödel. Int. Zschr. Vitaminforsch. 2(36):117-126, 1966.

Test doses of vitamin A palmitate, C¹⁴-labeled vitamin A acetate, D,L- α -tocopherol and S³⁵-labeled thiamine bromide hydrobromide were admin. by gastric sound or intracecal inj. (following laparotomy) to normally nourished and vitamin impoverished adult Wistar rats and to comparable groups of 1-wk.-old Wistar rats, with determination of hepatic conc. made 24 hr. after admin. of the first 3 vitamins and 1 hr. after admin. of thiamine bromide. Except for adult rats receiving vitamin B₁ intragastrically and nursing rats receiving vitamin A intracecally, resorption in vitamin-deficient animals was markedly reduced as compared to controls, independent of age or route of admin. The phenomenon was not attributed to decreased resorption ability, but was believed to be due to either some form of conditioned adaptation or some sort of damage to the intestinal wall. In all cases, there was less resorption from the distal portion of the gastrointestinal tract than there was from the proximal portion.

- 9626 IN VITRO ABSORPTION OF γ -GLOBULIN BY NEONATAL INTESTINAL EPITHELIUM OF THE PIG. (E.) Lecce, J. G. (North Carolina State U., Raleigh). J. Physiology (London) 184(3):594-604, 1966.

Uptake of fluorescent γ -globulin determined by a photomicroscopic technic with fixed sectioned tissues occurred within 15 min. in unfed neonatal pig intestinal slices. In vitro absorption by intestinal epithelium was limited to the neonatal pig and the 5-day-old mouse; no uptake of γ -globulin was seen in the intestines of mature mice, mature pig, pig with diarrhea, rabbit, guinea pig, chick, or chick embryo. Chick embryo yolk sac readily took up γ -globulin. Neonatal pig intestinal rings still absorbed γ -globulin after 4-6 hr. incubation; uptake required O₂ and Na and was reversibly inhibited by iodoacetate, arsenate, fluoride, 4,6-dinitro-cresol, phlorrhizin, anaerobiosis and cold, but not by large colloidal molecules. Similar results were obtained with chick embryo sacs. Treatment of mature pig intestinal epithelium with surface active agents did not produce nonspecific absorption artifacts resembling immature pig intestinal epithelium.

- 9627 EFFECT OF DIMETHYLSULFOXIDE ON THE INTESTINAL SUGAR TRANSPORT. (E.) Csáky, T. Z. (U. Kentucky, Lexington) and P. M. Ho. Proc. Soc. Exp. Biol. Med. 122(3):860-865, 1966.

A loop of small intestine of rats anesthetized with urethan was cannulated and perfused with 50 ml of various soln. Samples were analyzed for sugar each 15 min. The surface of the mucosa in a loop was estimated from its post-experimental dry weight. When the intestine was perfused with a 1:1 mixture of isosmotic sugar and isosmotic Na₂SO₄ (sugar conc. 148 mM) with varying conc. of dimethylsulfoxide (DMSO) it was found that DMSO more than doubled glucose absorption (suggesting a simple diffusion without a carrier), as it did glucose absorption; however, absorption of 3-methylglucose was not affected. Four per cent DMSO prevented the decrease in the rate of glucose absorption (saturation). The DMSO effect on glucose absorption was reversed when the perfusate was exchanged for one free of DMSO. If the relative DMSO-glucose mol. ratio was 1.0 or less no DMSO effect was present; the max. effect was produced by a ratio of approx. 2. The inhibition of transport of glucose by phlorrhizin (10⁻³M; an inhibitor of carrier-mediated aldose transport) was reversed by the presence of 4% DMSO. Neither 0.04 nor 4% DMSO enhanced glucose transport of 50 mg glucose isosmotic Na₂SO₄ soln. It was concluded that DMSO caused glucose and galactose to become sufficiently fat-soluble to bypass carrier mediation.

ABSORPTION

THE EFFECT OF BILE SALTS ON OXYGEN CONSUMPTION, OXIDATIVE PHOSPHORYLATION AND ATP-ase ACTIVITY OF MUCOSAL HOMOGENATES FROM RAT JEJUNUM AND ILEUM.

(E.) Faust, R. G. (U. North Carolina Sch. Med., Chapel Hill) and S.-M. L. Wu. *J. Cell. Comp. Physiol.* 67(1):149-157, 1966.

Mucosal homogenates of rat jejunum and of rat ileum in a special buffered medium were studied for the effect of bile salts upon oxygen consumption and oxidative phosphorylation by a polarographic method employing a Clark oxygen electrode coupled to an amplifier and recorder. ATPase activity was determined by measurement of inorganic phosphate produced under standardized conditions with and without the presence of bile salts. The bile salts inhibited oxygen consumption and uncoupled oxidative phosphorylation in homogenates derived from both jejunum and ileum. The bile salts increased ATPase activity in the presence of K^+ , Na^+ and Mg^{++} , in both homogenates from the jejunum and ileum. The decrease in ATP levels previously observed in the presence of bile salts can be accounted for by uncoupling of phosphorylation and increased ATPase activity. The bile salts may exert some regulatory role on the active transport of water-soluble substances across the mucosal layer of the small intestine.

USE OF POLYETHYLENE GLYCOL AND PHENOL RED AS UNABSORBED INDICATORS FOR INTESTINAL ABSORPTION STUDIES IN MAN. (E.) Schedl, H. P. (U. Iowa Coll. Med., Iowa City). *Gut* 7(2):159-163, 1966.

Use of polyethylene glycol (1; 1.0 g/liter) and phenol red (50 mg/liter) in an emulsified Ringer's buffer were perfused via a transintestinal tube into the duodenum of 13 normal volunteers, 9 patients with tropical sprue and one patient with Crohn's disease. The method of infusion and collection of samples was that of Schedl and Clifton. I was analyzed turbidimetrically, phenol red by measuring optical densities at 560, 520, and 600 m μ both in urine and intestinal juice. With 785 samples collected with normal patients there was a correlation of 0.94 between the two markers. In 292 samples in patients the correlation was 0.85. Analysis of 100 specimens of patients and normals failed to demonstrate I; however, phenol red was found in trace amounts in the urine of the patient group. It is concluded that both indicators are suitable for studies in normal subjects; I would generally be preferred because it is less absorbed.

FAT ABSORPTION IN PANCREATIC DEFICIENCY IN RATS. (E.) Masarei, J. (U. West. Australia, Perth) and W. J. Simmonds. *Gut* 7(2):114-118, 1966.

Anesthetized restrained rats prepared with a combined biliary and pancreatic fistula (48 hr. pretest) had emulsified olive oil, emulsified oleic acid or saline infused into the duodenum for 4 hr. (rate = 0.55 or 1.64 ml/hr.). Immediately thereafter the rats were killed and the contents of the stomach, small intestine and cecum recovered. Four groups were studied in each condition: indwelling duodenal tube but no fistula; combined biliary-pancreatic fistula, no replacement; combined fistula and replacement with taurocholate 16.5 mg/hr; combined fistula and taurocholate replacement plus bicarbonate 4.1 mg/hr. Saponifiable fat, lipolytic activity, tryptic activity were determined. Essentially no olive oil was absorbed in the absence of both bile and pancreatic juice. Addition of taurocholate did not significantly increase absorption; taurocholate and bicarbonate returned absorption to normal levels. Oleic acid was equally well absorbed in all groups. The test for trypsin was always positive in nonfistula animals and negative in fistula animals. A residual lipolytic activity was found in fistula animals although it was insufficient to give a positive trypsin test. No explanation was found for this finding but it is concluded that this residual lipolytic activity might account for the absorption of triglyceride.

THE INFLUENCE OF THE TEMPERATURE OF INTRALUMINAL CONTENTS ON FLUID TRANSIT AND ABSORPTION IN THE HUMAN INTESTINE. (E.) Love, A. H. G. (Queen's U., Belfast, Ireland). *J. Physiol. (London)* 185(2):80P, 1966.

Continuous state perfusions of a 50-cm segment of the small intestine in healthy human subjects was performed using a triple lumen tube technic. The perfusing electrolyte contained 1% polyethylene glycol as a non-absorbable marker to allow calculation of intestinal fluid vol. flow. Sulfobromophthalein was inj. through the

ABSORPTION

proximal tube and sampled from the distal tube so that a conc. curve could be drawn for measurement of transit time and segment vol. Perfusion studies above 37°C showed a 25% increase in water and Na absorption with no alteration in transit time whereas temperatures in the range of 17-25°C reduced water and electrolyte absorption by 32% with a reduction in transit time. A further decline in absorption and transit time occurred in the range of 5-10°C, at first, with a later increase in transit time being observed. Thus, absorption is not only affected by changes in transit time but also by other factors. The optimal temperatures for absorption in humans are similar to those found in an in vitro rat by Smyth and Taylor (1957).

- 9632 THE 3-METHYL-GLUCOSE TEST IN THE EVALUATION OF INTESTINAL ABSORPTION OF CARBOHYDRATES. (It.) Nordio, S. (U. Genoa, Italy), G. Vignola, A. Berio and G. M. Lamedica. Minerva Pediat. 18(14):730-733, 1966.

Since 3-methyl-glucose is not metabolized, the amount eliminated in the urine is directly proportional to that absorbed from the intestine; the optimum time for determination is 5 hr. after the oral loading dose. From an analysis of the distribution of values obtained in 37 control children, urine levels below 40% were considered abnormal. Four of 6 patients with malnutrition, 1 of 3 with fibrocystic disease, 5 of 10 with untreated celiac disease, 2 of 11 with treated celiac disease, and 1 of 7 with chronic enteropathies not due to gluten intolerance had values below 40%. Statistical analysis of the data suggests there is a defect in the mechanism for active transport of glucose in intestine of children with untreated celiac disease or malnutrition. During treatment of celiac disease, the absorption of 3-methyl-glucose increases more rapidly than that of xylose, a finding which correlates with the earlier regression of lesions in the more distal portions of the intestine, since xylose is absorbed in the upper and glucose in the more distal parts of the small intestine. The results in the patients with fibrocystic diseases (except in one case, in which intestinal lesions were present) are in accordance with the fact that the xylose test is usually normal in this disease.

- 9633 Fe^{59} ABSORPTION IN HUMAN SUBJECTS USING TOTAL-BODY COUNTING TECHNIC. (E) Pollack, S. (Walter Reed Army Inst. Res., Washington), S. P. Balcerzak and W. H. Crosby. Blood 28(1):94-97, 1966.

After an initial body count subjects were given 0.1 μc Fe^{59} i.v., 10 min. later the subject was again counted and drank 1.1 μc Fe^{59} in 50 ml H_2O with 1 mg ferrous sulfate. Four hr. after the p.o. dose the subjects were counted again. A whole body liquid scintillation counter and a crystal scintillation counter were used. The net count following the i.v. dose was subtracted from the count following the p.o. dose. Ideally the 2 values should have been equal if there were no differences in the efficiency of the gastrointestinal and circulating Fe^{59} counts. Five patients were counted, 4 hourly after i.v. Fe^{59} . After 10 min. no changes in counts were found indicating high reproducibility. Differences as great as 25% between the 2 doses occurred in the liquid counter and as high as 35% in the crystal counter. It is concluded that the common assumption of equal counting efficiency of Fe^{59} located mainly in the gastrointestinal tract and Fe^{59} distributed in the body is not justified. It is also suggested that the error of counting the oral dose can be avoided by giving a calibrating i.v. dose of Fe^{59} before or after the p.o. dose. The correction could be made with the formula: % absorbed =
$$\frac{S_2(ST_1) - S_1}{ST_2} \cdot \frac{100}{(Y/X) S_1}$$

where Y = μc in p.o. dose, X = μc in i.v. dose, ST_1 = standard count at beginning, ST_2 = standard count at end, S_1 = Subject count at beginning, S_2 = Subject count at end.

- 9634 A NOTE ON PERFUSION WITH LABELLED COMPOUNDS TO DETERMINE INTESTINAL ABSORPTION. (E.) Knoll, K. R. (Butler U., Indianapolis, Ind.), R. P. Parke and H. A. Swartz. J. Pharm. Pharmacol. 18(8):540-542, 1966.

The duodenal and ileal ends of the intestine were cannulated in anesthetized female Wistar rats, the stomach and cecum being closed off by ligatures. The intestine was replaced in the abdominal cavity and perfusion started at a rate of 1.5 ml/min. Soln. were maintained at 37°C, the intestine was cleared by 30 min. of perfusion of

ABSORPTION

g-free soln. followed by 30 min. of drug soln., collections were made at 10-min. intervals thereafter. This procedure was followed with 5 rats for each of 3 drug solns. (mM/liter water); 1) Salicylic acid, 1.0; NaCl, 145; KCl 4.56; CaCl_2 1.26; H_2PO_4 1.33; NaH_2PO_4 0.33. 2) as in 1) plus phenylephrine HCl 0.03; and 3) as in 1) plus caffeine 0.09. Five $\mu\text{C}/300$ ml of C^{14} -carboxyl-labeled salicylic acid was added to each soln. Samples of perfusate (0.1 ml) were counted by a liquid scintillation detector and associated beta spectrometer, the activity being compared to soln. samples collected before perfusion. The intestinal absorption of salicylic acid was observed to be 40.7, 43.2, and 44.9% at 10, 20, and 30 min.. When phenylephrine was present absorption was increased to 67.7, 68.6, and 67.3%, when caffeine was present to 71.5, 72.9, and 73.3% at 10, 20 and 30 min. It is concluded that the perfusion method is preferable to chemical assay procedures because of its sensitivity and specificity. In particular, it was possible to do the assay in the presence of phenylephrine which chemical methods are unable to do.

5 THE EFFECT OF LEUCINE ON THE UPTAKE OF GLUCOSE. (Hun.) Szigeti, A. (Nat. Inst. Nutrition, Budapest) and M. Bedo. Kiserl. Orvostud. 18(3): 280-284, 1966.

Three sets of experiments performed on adult, fasting rats of both sexes are described: 1) Two groups of 5 rats each fasted 24 hr. received 3.0 ml of 3% leucine or + 20% glucose by gastric intubation; 3 controls received only glucose. Twenty-four rats under Nembutal anesthesia (4 mg/100 g) were perfused through the small intestine with a soln. containing 1% leucine + 5.4% glucose, for 2 hr. Twenty controls had only glucose. 3) Thirty-two rats were fed daily 150 mg/kg leucine (by gastric intubation) for 12 days and received on day 13 a perfusion with 5.4% glucose in 2. Blood sugar levels were checked at 30-min. intervals starting immediately after conclusion of each experiment. In experiments 2 and 3 blood sugar and liver and muscle glycogen levels were also measured during perfusion. The first experiment confirmed the known hypoglycemic action of leucine (blood glucose values returned to the initial levels within the hr. while the normal curve was still above the initial level after 3 hr.); however, this effect was observed only when blood glucose levels themselves were increased. Normal values were not lowered either simultaneously or by preceding leucine admin. The 2 other experiments showed that sugar resorption through the intestines is not influenced by leucine, and that the differences between liver and muscle glycogen levels of controls and leucine-treated animals is insignificant.

6 EXPERIMENTAL STUDIES ON THE INTESTINAL ABSORPTION OF VITAMIN B. (Jap.) Kochi, T. (Tokushima U. Sch. Med., Japan). Acta Paediat. Jap. (Overseas) 7(14):50-51, 1966.

Intestinal absorption of thiamine chloride and B_1 derivatives was studied in rat intestine sections by Wiseman's method. Forty ml of Tyrode's soln. with 12.5 γ /ml thiamine chloride or a derivative in soln. was circulated through the lumen of the intestine, 100 ml soln. without B_1 was circulated around the serosal surface of the preparation. The amounts of vitamin transferred from mucosal to serosal soln. at 30 min. and into intestinal tissue at 60 min. were determined. Thiamine present in mucosal soln. at 30 min. and 4.9% after 60 min.) transferred to serosal soln.; 24.7% and 4.1% of these were esterized. Vitamin B_1 derivatives, TPD and BTMP, mucosal soln. to serosal soln. transfer was approx. double that of thiamine chloride. TPD transfer to intestinal tissue was 4.4%, BTMP 4.1%. Transferred thiamine showed a preference for free thiamine. The ester rate was highest for thiamine chloride followed by BTMP and TPD. The ester, TPD, BTMP rate of transfer to intestine was more than to serosal soln.; 77.9% TPD and 44.1% BTMP converted to free thiamine in 60 min. in mucosal soln. Thiamine absorption into intestine and serosal soln. was more in thiamine chloride soln. + ATP than without. DNP inhibited thiamine transfer to serosal soln. It was concluded phosphorylation is involved in intestinal absorption of thiamine chloride; absorption of TPD and BTMP depends on their affinity for lipid.

TRANSPORT OF L-CYSTINE AND L-DJENKOLIC ACID BY THE IN VITRO SMALL INTESTINE. (E.) Spencer, R. P. (Yale U. Sch. Med., New Haven), K. R. Brody and F. Vishno. Life Sci. 5(13):1163-1167, 1966.

ABSORPTION

Fasted hamster and mouse everted small intestine sacs were filled with and placed in pH 7.4 Krebs-bicarbonate buffer (no glucose present) containing various conc. of L-cystine- H^3 or L-djenkolic acid- H^3 . Hamster intestine was divided into 3 or 6 sacs; mouse intestine was divided into 3 sacs. The sacs were incubated at $37^\circ C$ for 1 hr. and the mucosal and serosal soln. assayed by liquid scintillation counting. Inhibition studies were carried out by adding nonlabeled amino acids to the soln. used. In the absence of glucose H_2O transport was small (0-0.1 ml) and in the mucosal to serosal direction. Increases in serosal radioactivity represented transport. L-Djenkolic acid, $1 \times 10^{-4} M$, yielded a conc. of 1.04 (serosal/standard). In the fifth sac 2.6 times as much L-cystine ($1 \times 10^{-4} M$) was transported (5/6 the way down the intestine) as in the first. In the fifth sac L-djenkolic acid transport was demonstrable in 10/22 preparations. In mouse gut sacs transport of L-djenkolic acid was demonstrable at conc. of $1 \times 10^{-4} M$ to $1 \times 10^{-3} M$. The max. transport of L-djenkolic acid by mouse intestine was approx. $0.3 \mu moles/g$ tissue; the apparent Michaelis constant was approx. $2 \times 10^{-4} M$. Transport of $5 \times 10^{-4} M$ L-djenkolic acid was inhibited more than 90% by $5 \times 10^{-3} M$ L-lysine. At max. L-cystine conc. below $1 \times 10^{-3} M$ there was no inhibition of $1 \times 10^{-4} M$ L-djenkolic acid.

STUDY OF PERORAL COLONIC AND PERITONEAL ABSORPTION IN NORMAL AND

PATHOLOGICAL CONDITIONS USING A DYE. (E.) Sedky Abdou, M. (Cairo U., U.A.R.), E. Salem, G. Magahed and M. Danasoury. *Gut* 7(3):282-284, 1966.

Phenol red was chosen as an indicator substance because of its complete and rapid excretion by the normally functioning kidney and its safety from irritation. In 5 normals and 14 patients with ascites and cirrhosis of the liver, following 2 glasses of water 5 ml of 0.6% soln. of phenol red in 250 ml of water was admin. p.o., urine was collected for 4 hr. and content of dye determined by colorimetry. The ingested dye was recovered in 12.4-17.5% normals. In all pathologic conditions there was impairment: in patients with ascites due to heart failure 9.6% was recovered; in tubercular and malignant ascites, 8%; in cardiac cirrhosis, 7.6%; and in bilharzial cirrhosis, 3.4%. Following i.p. admin. of 1 ml of 0.6% soln. in 50 ml Ringer's soln. to 5 normals, 8 cases of ascites and 6 cases of liver cirrhosis, 70-80% of the dye was recovered in normals, compared to 73-77% in cases of ascites due to congestive heart failure. In bilharzial ascites i.p. absorption was down to an av. 50.5%. Dye excretion was impaired in cases of cirrhosis of any origin. The most marked impairment was seen in localized peritoneal diseases. Colonic absorption was studied by means of 2 ml 0.6% phenol red in 250 ml warm water being slowly instilled into the colon. This test was performed in 5 normals, in 8 cases of ascites, in 6 cases of liver cirrhosis and in 5 other cases of colonic disease. The recovery in normals was 6-11.4%. In ascites the values were all in or near the normal range. Impairment was present in all cases of cirrhosis; bilharzial cases av. half the normal absorption. Variable absorption was noted in the cases of colonic disease depending on diagnosis. In all cases kidney function tests were performed to assure normal kidney functioning. It is concluded that the series of tests might be useful in diagnosis. In particular the i.p. test would be helpful in the diagnosis of local peritoneal affections. In cases of cirrhosis of the liver impaired absorption correlated well with the rise in portal pressure which is an index of the degree of liver affection.

HISTOCHEMICAL AND BIOCHEMICAL ANALYSIS OF THE NONSPECIFIC ESTERASES OF THE SMALL INTESTINE OF THE RAT. (E.) Friedman, B. (U. Michigan Sch.

Med., Ann Arbor), D. S. Strachan and M. M. Dewey. *J. Histochem. Cytochem.* 14(7):560-566, 1966.

Adjacent 5-mm segments were cut from rat small intestine 2 cm from the pyloro-duodenal junction, trimmed free of mesentery and washed with 0.9% NaCl. For starch gel electrophoretic studies 0.02-ml samples of supernatants of centrifuged homogenates were incubated for varying times in filtered soln. containing $2.5 \times 10^{-4} M$ naphthyl acetate or naphthyl butyrate. For quantitative assay the amount of α -naphthol released during the first 20% of hydrolysis was determined. Assays were performed on a recording spectrophotometer at 322 $m\mu$ and 307 $m\mu$ for α -naphthyl and α -naphthyl butyrate, resp. Protein conc. were determined by the method of Lowery et al. (1951). For histochemical studies segments were frozen in isopentane and

RPTION

ioned in a cryostat at $4-6\ \mu$, placed on a slide dried for 5 min. and fixed in ol-calcium for 10 min. followed by washing and placing in substrate soln. similar to those used for the starch gels. With α -naphthyl butyrate and α -naphthyl acetate substrates, esterase activity was shown in the crypts and epithelium. This distribution of enzymatic activity did not correspond to the distribution of the absorptive epithelium." Electrophoresis showed a spectrum of active fractions which hydrolyzed both substrates. The number of enzymic fractions was the same for both substrates as were their mobilities. The butyrate ester was hydrolyzed 10 times faster than the acetate ester.

EFFECT OF SUGARS ON TRANSPORT OF ALANINE IN INTESTINE. (E.) Chez, R. A. (Harvard Med. Sch., Boston, Mass.), S. G. Schultz and P. F. Curran. *Science* 153(3739):1012-1013, 1966.

Experiments were performed using rabbit distal ileum in a modified Krebs-Ringer-bicarbonate soln. (140 mM Na and 12 mM P). Transmural flux of alanine across the intestine from mucosal to serosal soln. was measured. In each experiment adjacent pieces of intestine served as controls; the other piece was in soln. containing 20 mM galactose or glucose and the tissues were bathed on both sides with 5 mM alanine soln. Alanine labeled with C^{14} was added to the mucosal soln. Radioactivity was assayed in a liquid scintillation spectrometer. Influx of alanine from the serosal soln. into the cells was measured by the method of Fuisz *et al.* Cellular accumulation of alanine was determined on mucosal strips incubated in soln. containing C^{14} alanine. Extracellular space was estimated by using H^3 -inulin. The steady state flux of alanine was found to be lower in the presence of sugar; 20 mM glucose inhibited 53%, 20 mM galactose inhibited 34%. Galactose (20 mM) reduced the ratio of cell to medium conc. of alanine 32% after 30-min. incubation. Phlorizin (4 M) completely inhibited the effect of galactose on the accumulation of alanine. Neither sugar had any effect on the influx of alanine across the mucosal membrane. These findings are similar to those reported for other species.

THE EFFECT OF BODY POSITION AND pH ON THE GASTROINTESTINAL ABSORPTION OF SALICYLATE AND CREATININE IN MAN. (E.) Gibaldi, M. (Coll. Pharm., Columbia U., N. Y.) and J. L. Kanig. *Arch. Int. Pharmacodyn.* 161(2):343-358, 1966.

Salicylate sodium salicylate (0.3 g) and creatinine (2.0 g) were admin. to healthy male subjects in 25 ml distilled water. The subjects were fasted 9 hr. before and 9 hr. after admin. The test soln. was ingested either ambulatory or supine (left lateral position) and maintained in this state for 1 hr. After either salicylate or creatinine soln., 175 ml of water, 0.01 N HCl, or 0.5% Mg trisilicate suspension was admin. Urine samples were collected before admin. and at 1-24 hr. Urine pH was determined on collection, subjects with urine pH greater than 6 were dropped from the study, ascorbic acid (2 g) was admin. before test as a urine acidifier. The salicylate conc. was determined colorimetrically; salicyluric acid was determined separately. Creatinine conc. was determined colorimetrically; daily excretion curves were determined. No measurable excretion of salicylic acid occurred as long as urine was maintained at pH 6; regardless of conditions, salicylurate accounted for 90% of the given dose. The left lateral supine position decreased urine metabolite levels; trisilicate in this position depressed acid and decreased urine salicylurate levels. The antacid in ambulatory patients had no effect. The left lateral position and HCl decreased urine creatinine levels; the antacid plus the supine position increased urine levels. Creatinine and salicylate excretion rates were found to be linear when plotted on semilog coordinates. It is concluded that gastric retention promoted salicylate absorption but depressed creatinine absorption. Simultaneous admin. of a soln. which resulted in an increase in the fraction of undissociated species at the absorption site increased absorption, and *vice versa*. The results are considered to be in agreement with the pH-retention hypothesis of drug absorption.

ABSORPTION

- 9642 STUDIES ON THE RESORPTION OF CITRIC ACID IN THE GASTRO-INTESTINAL TRACT OF RAT SUCKLINGS. (Ger.) Behnke, U. (Inst. Nutrition, German Acad. Sci., Berlin), H. A. Ketz and K. Täufel. Acta Biol. Med. German. 16(5): 514-523, 1966.

Wistar rats (10 g, 10 days old, both sexes) were admin. intragastrically 4.0 mg acid in 0.1 ml saline (400 mg/kg), sacrificed by decapitation at 30-min. intervals. Citric acid contents of blood, urine, stomach, small intestine (with appendix), and large intestine determined. Aconitate hydratase and isocitric dehydrogenase activities of the mucosa of small intestines were also measured. A detailed statistical analysis of these results is presented and compared with data previously obtained from adult rats. In both age groups, citric acid is continuously removed from the stomach; resorption and metabolism occurring in the small intestine; no citrate reaches the large intestine; blood citrate levels are temporarily elevated. It is shown, however, that resorption of about 85% occurs in adult rats in the first 90 minutes while the same time period represents only a "lag" phase in the sucklings. As a result, citric acid is considerably delayed in reaching the small intestine; once the small intestine is reached the acid remains much longer, i.e. its resorption and metabolism are very slow. Blood levels of the young, normally twice the blood level of adults, increases only slightly and at a slow rate. In addition, intestinal enzyme activity of the young is also less than that of adult rats. The data show a delayed metabolism of citric acid in suckling rats. The importance for understanding of human infant nutritional problems is discussed.

- 9643 ELECTRICAL ACTIVITY OF THE INTESTINE IN RELATION TO METABOLIC EXCHANGES MODIFIED BY ABSORPTION AND MOTILITY. (Fr.) Thouvenot, J. (U. Tours Sch. Med. Pharm., France) and A. Rougureau. Path. Biol. (Paris) 14(11-12/13): 682-691, 1966.

Electrical activity was recorded by means of electrodes of silver chloride, fine strips of tungsten fashioned into points, or bipolar needle electrodes (Bronk type) in the saturated silver chloride soln. retained by a slight negative pressure produced by a water aspirator. The electrodes can be bipolar with an amplifier in circuit, or monopolar coupled to an amplifier with the indifferent electrode grounded and feeding into a preamplifier and amplifier; the varying electrical currents were recorded upon a cathode ray oscillograph or traced by an ink-writing unit. The animal was prepared for study; it was first anesthetized (ether or urethane). The animal was kept warm on a thermostatically controlled table. A plexiglas cover was fitted to the abdomen; this was drilled to permit the passage of the electrodes and was the means of observing the viscera using dissecting binoculars. Inlets allowed the irrigation of the viscera to change the ionic composition of the fluid bathing the gut. The contents of the lumen could be varied; cooling could be accomplished as well as pressure excited. The *in vitro* experiments were carried out in a thermostatic bath where all the above techniques could be carried out in a balanced buffered saline soln., isosmotic, having a pH of 7.3, and containing glucose. The potential difference observed in the intestine of the rat, guinea pig and the cat was under normal conditions of the order of 500-700 μ V. The measurement of these potentials furnished an indication of functions related to metabolic activity. These studies differentiated the fundamental rhythmic electrical activity (FREA) and the rapid potentials arising prior to the contraction of muscle (the action current). This work on the basic electrical activity could possibly lead to information concerning metabolic and endocrine factors. FREA depends upon the temperature, but also on mechanical stretch and irrigation; it is also influenced by ionic and local metabolic conditions. The complexity of these factors can be resolved into Lissajous' curves.

- 9544 INTESTINAL ABSORPTION OF ERUCIC ACID AND ITS INCORPORATION INTO THE LYMPHATIC CHYLOMICRONS OF THE RAT. (Fr.) Savary, P. (U. Marseille Sch. Sci., France) and M. J. Constantin. Biochim. Biophys. Acta 125(1): 118-128, 1966.

Male white rats (4-5 mo. old) maintained for 4 wk. on a balanced diet which contained 5% lipids were fasted for 24 hr., then 4 hr. before operation they received cooked polished rice which contained 5% olive oil. A fistula was established on the

thoracic duct; the rats were placed in their cages under restraint. It was evident that the lymph lacked chylomicrons and that its flow became regular requiring about 1 hr. The rats were then fed free erucic acid, or a mixture of 2 molecules of this acid and 1 molecule of oleic acid, or trierucin. The lymph was saved and the chylomicrons separated by centrifugation, the lipids extracted and analyzed. In some cases the triglycerides of the high molecular wt. lipoproteins thrown down by centrifuge were also analyzed. The mixture of boiled rice and erucic acid appeared to be unpalatable to the animals so that the fatty acid was admin. by gastrotubation. Immediately afterward 1 ml of 0.9% NaCl was introduced into the stomach. The extraction of lipids from feces and intestines was accomplished by a mixture of chloroform and methanol (2:1) with 2% formic acid added to decompose the esters which eventually form. When rats are fed either erucic acid or trierucin, the intestinal absorption of each of those compounds is non-quantitative. Only reduced amounts of triglycerides are found in lymph of the thoracic duct. These glycerides contain 30-40% of C₁₄ and C₁₈ chains, very likely of endogenous origin. These fatty acids were analyzed and their distribution between internal and external positions in lymph triglycerides studied. Erucic chains when ingested in the free form in a mixture with oleic acid, are more numerous in external than internal position of the triglycerides. In this respect, the behavior of erucic and stearic acids is somewhat similar. Erucic acid seems to be an example of a lipid which is poorly absorbed in spite of the fact that it is a liquid at 37°C and readily soluble in alkaline bile salt soln. When rats are fed oleic acid, a compound which is well absorbed in the intestine, endogenous contamination results in chylomicron triglycerides because interconversions readily occur from oleic acid.

SURGICAL TREATMENT OF MASSIVE SMALL BOWEL LOSS. PHYSIOLOGIC RESPONSE TO REVERSED SEGMENTS, RECIRCULATING LOOPS AND TONIC SEGMENTS IN DOGS. (E.)
Singleton, A. O. (U. Texas Med. Branch, Galveston). *Am. Surg.* 32(7): 437-441, 1966.

Experimental procedures designed to increase absorption after massive loss of intestine are reviewed. It is concluded that substantial adaptation is achieved by the organism itself in many cases. Resections (50%) of the small intestine including the ileocecal valve were performed in 23 dogs. One group of 8 had, in addition, a 6-in. reversed segment; a second group also had a reversed 15-in. segment. The dogs without reversed segment lost an av. 9.7 pounds; dogs with the 6-in. reversed segment lost an av. 7.6 pounds; the 15-in. reversed segment group lost an av. 3.6 pounds. Four of seven dogs in the control group and 2 of 8 in the 6-in. reversed segment group died within 2 mo.; none of the animals in the 15-in. reversed segment group died. Transit time in both of the reversed groups was not significantly altered; transit time in the control group was accelerated. Stools were semi-liquid in the control group and semi-soft in both experimental groups. Only the dogs in the 15-in. reversed segment group were able to regain their pre-operative wt. The accuracy of iodine fat absorption studies is questionable but there appears to be some advantage with the larger reversed segment. It is concluded on the basis of both animal and human data that there did not appear to be a substantial advantage to any one procedure, but reversal of short segments would seem preferable.

THE EFFECT OF CHAIN LENGTH ON THE ACTIVATION AND SUBSEQUENT INCORPORATION OF FATTY ACIDS INTO GLYCERIDES BY THE SMALL INTESTINAL MUCOSA. (E.)
Brindley, D. N. (U. Birmingham, England) and G. Hübscher. *Biochim. Biophys. Acta* 125(1):92-105, 1966.

In this series of determinations all reagents were of the highest purity; these included a long series of fatty acids: C₄:0, C₆:0, C₈:0, C₁₂:0, C₁₄:0, C₁₆:0, C₁₈:0, C₁₈:1, C₁₈:2, C₁₈:3, also trybutyrine, methyloleate, monopalmitin, 1-glycerophosphate, ATP and Coenzyme-A (CoA) among others including radioactive fatty acids labeled with C¹⁴. A modification of the hydroxamic acid method for assaying acyl-CoA was used. Cat intestinal mucosa showed max. reaction rates for CoA esters with palmitate and stearate, unsaturated fatty acids giving much lower reaction rates than their saturated analogs. Comparison of activities of the homogenized with the microsomal fraction showed that acetyl CoA synthetase and one of the CoA-synthetases were not of microsomal origin. The microsomal fraction of the

ABSORPTION

guinea pig intestinal mucosa had max. reaction rates for acyl CoA syntheses with myristate; unsaturated acids had similar rates to their saturated analogs. The incorporation of fatty acids into glycerides by the total homogenate of the cat intestinal mucosa was studied. Using L-3-glycerophosphate and single fatty acids, max incorporations were obtained with myristate, palmitate and stearate. A different pattern of incorporation was found with 2-monopalmitin, 1-monopalmitin and 1-monolein, but again the preference was for long chain acids. If equimolar mixtures of acids were substituted for the single fatty acids, then irrespective of glyceride-glycerol precursor, myristate was incorporated to the greatest extent. It is suggested that the specificity of the enzymes studied contributes to the partition of fatty acids between portal blood and chyle during fat absorption.

SECRETIONEFFECT OF DENERVATION AND SUBSEQUENT RESECTION OF ANTRAL POUCHES ON SECRETION FROM HEIDENHAIN POUCHES IN RESPONSE TO GASTRIN AND HISTAMINE.

(E.) Andersson, S. (VA Ctr., Los Angeles, Cal.) and M. I. Grossman.

Gastroenterology 51(1):4-9, 1966.

Greyhounds, 13-17 kg in wt., were provided with Heidenhain pouches and 2-3 wk. After vagally-innervated antral pouches were constructed in the same animals. Following recovery from the second operation, a series of tests was begun; on completion of this series, the antral pouches were completely isolated from the stomach by severing all neural and vascular connections, the only attachment being to the body from which the blood supply was derived. After recovery the second series of tests was performed. A final operation removed the antral pouches; upon recovery, a third series of tests was carried out. The tests determined the dose response curves for histamine and gastrin. Samples of gastric juice were collected every 15 min. from the Heidenhain pouches. Volume, titratable acidity and pH were recorded; pH in conc. was estimated using radioiodinated serum albumin as substrate. The pH of the untreated antral pouch secretion was never found to be less than 7. Acidification of antral pouches was by perfusion with the 0.1 N HCl at the rate of 80-100 ml/hr. pH of the effluent varied between 1.2 and 1.6. Histamine dihydrochloride was given in doses ranging from 0.2-6.4 mg/hr. Gastrin (expressed as wet wt. of the hog stomach from which it was derived) ranged in doses from 2.5-40 g/hr. Two to 7 trials of each of stimulant were made on each of the 4 dogs in each of the 3 series of tests. Denervation of the antral pouches reduced production of acid in the Heidenhain pouches to submaximal, but not to max. doses, of histamine. Removal of the denervated pouches caused no further reduction. With 2.5-5-g doses of gastrin, no difference was seen between innervated and denervated antral denervation decreased acid production. After antrectomy the response to 2.5 and 5.0 g doses increased; the response to larger doses was unchanged. Acid perfusion of the innervated pouch markedly repressed the response to histamine; this inhibition completely disappeared after denervation. Very high doses of gastrin (20 and 40 g/hr.) showed a decreased acid output when the antral pouch was being perfused. After denervation of pouch, perfusion had no effect on the response to gastrin except at the 5 g/hr. dose which increased acid secretion. After denervation of antral pouch pepsin output decreased with the lowest dose of histamine; after antrectomy pepsin output increased with the middle dose of histamine. The output of pepsin in response to graded doses of gastrin was independent of denervation and removal of the antral pouch.

THE EFFECT OF METHYL DOPA UPON PANCREATIC SECRETORY RESPONSE TO INTRA-JEJUNAL HYPERTONIC GLUCOSE SOLUTION. (E.) Hudock, J. J. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.), P. Vanamee and W. Lawrence, Jr.

Surgery 60(2):443-448, 1966.

Pancreatic response to hypertonic feedings was studied before, during and after intrajejunal admin. of methyl dopa in dogs. Six dogs were prepared for intermittent occlusion of the pancreatic duct by introduction of a modified duodenal cannula and ligation of the accessory pancreatic duct. A cannula was also placed in the gastric antrum to allow external drainage of gastric juice during the experiment. After recovery, the dogs were fasted 24 hr., lightly anesthetized, and infused i.v. with secretin to produce a uniform flow of pancreatic juice during baseline measurements. Intrajejunal feedings of 200 ml of 50% glucose were made through the duodenal cannula using a balloon catheter. After 60 min. of baseline measurements of volume at 5-min. intervals, determination of total CO₂, pH, and amylase activity of pancreatic secretion, the hypertonic sugar soln. was instilled over a 5-min. period and measurements continued for 1 or 2 hr. Volume output changes were most marked during the first 30 min. after feeding. The mean pancreatic flow rate after instilling the standard vol. of glucose (in percent of baseline flow) was: during treatment control period 56.9 ± 2.7 ; after 14 days of methyl dopa (500 or 750 mg/kg/day), 91.0 ± 3.1 ; after 21 days of methyl dopa 98.4 ± 1.3 ; 8-14 days after cessation of methyl dopa treatment, 51.9 ± 2.6 . It is suggested that methyl dopa, which is both a serotonin antagonist and a norepinephrine inhibitor, may be of use in treating the dumping syndrome.

SECRETION

9654

EFFECTS OF HISTALOG AND SECRETIN ON GASTRODUODENAL PROFILE OF pH, POTENTIAL DIFFERENCE AND PRESSURE IN MAN. (E.) Andersson, S. (VA Ctr., Los Angeles, Cal.) and M. I. Grossman. Gastroenterology 51(1):10-17, 1966.

Subjects were fasted overnight. The probe containing sensors for pH, potential difference (PD), and pressure was introduced through the nose and positioned in the distal part of the duodenum by fluoroscope; the PD circuit was completed by immersion of the subjects finger in saturated KCl soln. containing a calomel half-cell yielding skin-to-lumen measurements. Recording was begun and then the probe was withdrawn in 1-cm steps with a 30-60-second pause for recording at each step. Withdrawal was continued until the probe was in the stomach. The probe was again repositioned in the distal duodenum. Recording was begun again 15 min. after i.m. of Histalog, 1.5 mg/kg body wt. (22 patients), or secretin was given as a single, rapid i.v. dose of 75 clinical units (15 patients). Histalog was also admin. to 3 patients having pernicious anemia. The decrease in gastric pH caused by Histalog was usually reflected in an accompanying decrease in pH of the bulbar portion of the duodenum; pH of the postbulbar region did not decrease in association with the stomach or duodenal bulb. Histalog did not lower the gastric pH in the 3 patients with pernicious anemia; these 3 patients had positive PD values for the oxyntic gland areas of the stomach whereas normal individuals had negative values, the PD values for the gastric antrum of anemia patients and control subjects were about the same. Inj. of secretin caused an increase in pH that extended from the postbulbar region of the duodenum to the gastric antrum. In most subjects motor activity occurred within 2 min. after inj. of secretin and lasted for an av. of 5 min.

9655

EFFECT OF ANTISECRETORY DRUGS ON GASTRIC HYPERSECRETION IN ENDOCRINE-ADENOMA SYNDROMES. (E.) Cook, H. B. (Central Middlesex Hosp., London) and J. E. Lennard-Jones. Lancet 2(7457):247-250, 1966.

Gastric acid hypersecretion was present in 3 patients with endocrine-adenoma syndromes. Max. secretion (following histamine 0.04 mg/kg or ametazone 1.5 mg/kg) in two patients was only slightly greater than basal secretion. Hexamethonium (50 mg) and atropine (0.4 mg i.m.) dropped acidity only 59 and 68% in 2 cases; the third case, the one showing a response to ametazone, showed temporary anacidity. Hexamethonium (50 mg) admin. to 1 patient produced a suppression equal to hexamethonium (50 mg) + atropine (0.4 mg i.m.). Poldine (anticholinergic) admin. over 12 days (up to 14 mg 4 times per day) reduced spontaneous gastric secretion, while ametazone-stimulated secretion was only slightly reduced. Sixteen mg of poldine intraduodenally completely inhibited gastric secretion. The value of the admin. of hexamethonium and atropine in the diagnosis of the Zollinger-Ellison syndrome is suggested. Persistent gastric acid secretion after anticholinergic-ganglion blocking drugs may provide evidence of a gastrin-secreting tumor.

9656

THE EFFECT OF SHAM FEEDING ON THE SECRETION AND MOTILITY OF CANINE DUODENAL POUCHES. (E.) Preshaw, R. M. (McGill U., Montreal, Canada) and R. S. Knauf. Gastroenterology 51(2):193-199, 1966.

Three mongrel dogs were prepared with an esphagostomy (Olbe's method) and a pouch made from a segment of the duodenum, maintaining vagal innervation (pylorus to 1 cm above the bile duct) draining via a mucocutaneous fistula. Gastrojejunostomy re-established intestinal continuity. A metal cannula forming a gastric fistula was placed in the most dependent portion of the stomach. Three wk. elapsed postoperatively before testing. After 18 hr. fast gastric and duodenal juices were collected for basal levels. Sham feeding was performed with 200 g meat, duodenal secretion was also collected following true feeding with 600 g dog food. Duodenal pouch motility was recorded after sham and real feeding by means of a saline-filled balloon. Sham feeding significantly increased gastric acid and pepsin secretion over a period in excess of 150 min. The volume and output of pepsin-like activity of the duodenal pouch were transiently increased. Duodenal pouch motility in 7 of 12 experiments was increased for periods up to 90 min. True feeding, with esophageal and gastric fistulae closed, increased secretion of duodenal juice and increased pepsin-like activity. Peak secretory rates were 1.8 ml/15 min. compared to 1.0 ml/15 min. following sham feeding. Duodenal motility increased following true feeding in all of 6 experiments.

- 7 DOSE-RESPONSE CURVES OF DENERVATED AUTOGENOUS AND HOMOTRANSPLANTED CANINE FUNDIC POUCHES STIMULATED WITH PURIFIED GASTRIN AND HISTAMINE. (E.) Davidson, W. D. (U. California Sch. Med., Los Angeles), I. A. Daves, C. A. Lemmi, J. H. Miller and J. C. Thompson. Gastroenterology 51(2):180-192, 1966.

effects of histamine and gastrin were studied in four types of denervated fundic pouches in 38 dogs: 6 with Heidenhain pouches (I), 7 with I with denervated antral pouches (II), 7 with I with antrectomy (III), and 9 dogs with heterotopic homotransplanted fundic pouches with a homotransplanted antral pouch (IV). Azathioprine, prednisolone, and actinomycin C were used for immunosuppressive therapy in IV dogs. Animals were fasted 16 hr. before testing, histamine was infused (i.v. 0.01 to 0.1 mg/kg/min.), and gastrin (0.0005 to 0.625 μ g/kg/min.); each dose level was administered for 1 hr., juice was collected each 30 min., only data from the second 30 min. were analyzed. Histamine acid secretion dose response curves were similar in all groups; gastrin was somewhat more sensitive to submaximal doses. Max. acid secretion was decreased in II and enhanced in IV. Supramaximal doses of both histamine and gastrin inhibited acid secretion, except IV for gastrin. On a molar basis gastrin was 570 times more potent than histamine in stimulating acid secretion. The histamine dose response curves were similar for all groups, higher doses decreased pepsin output while acid and vol. still increased. Except in I dogs the pepsin response to gastrin was similar to that stimulated by histamine. In I dogs pepsin output continued to increase with gastrin dosage. Antrectomy and antral denervation abolished the marked pepsinogenic response of denervated fundic pouches to gastrin stimulation. It was concluded that on the basis of these findings, the physiological role, if any, of gastrin in stimulating pepsin secretion in the intact stomach is unknown.

- 8 THE ABSENCE OF LARGE FUNCTIONAL ARTERIOVENOUS SHUNTS IN THE STOMACH OF THE ANESTHETIZED DOG. (E.) Shoemaker, C. P., Jr. (Albany Coll. Med., N. Y.) and S. R. Powers, Jr. Surgery 60(1):118-126, 1966.

Eight mongrel dogs were cannulated for introduction of radioactive microspheres (10 μ in diameter) into the gastric arteries and for recovery of gastric venous blood. Presence of gastric venous blood to show radioactivity above background levels showed absence of arteriovenous shunts 50 μ or more in diameter were not functioning in the stomach. Inj. of epinephrine (0.2 ml. i.v.) prior to inj. of microspheres did not lead to recovery of the latter in venous outflow. Inj. of pitressin i.v. decreased gastric blood flow and gastric venous O_2 tension. Infusion i.v. of small amounts of histamine increased gastric venous blood flow and O_2 tension; higher amounts reversed the phenomenon in the presence of profound hypotension. Epinephrine (i.v.) induced an initial increase, then a fall, of blood pressure, accompanied, in some animals, by an initial decrease and then a marked increase of gastric venous blood flow. Max. increase of gastric venous O_2 tension was always reached after gastric venous blood flow had reached its max. O_2 consumption also increased with the increase of gastric venous blood flow. Active gastric acid secretion was accompanied by decrease of gastric venous CO_2 tension, shifting the O_2 -dissociation curve to the left.

- 9 GASTRIC SECRETORY CHANGES RESULTING FROM GASTRIC HYPOTHERMIA. (E.) McIntyre, J. A. (St. Joseph's Hosp., Toronto, Canada) and R. Brindis. Brit. J. Surg. 53(5):439-445, 1966.

Twenty-nine patients with radiologically demonstrable duodenal ulcer crater or absence of a previous crater suffering recurrent hemorrhages, recurrent symptoms of previous hemorrhage or perforation or intractable ulcer pain were treated for 10 min. of gastric hypothermia by Wangenstein's method (stomach-shaped balloon inflated with 800-1200 ml of -17° alcohol). Measurements of overnight gastric secretion (8 hr.) and the effects of 15 U insulin and 100 ml of 10% peptone broth were obtained before, 12 hr. and 3 mo. after freezing. Vol., pH and total acidity were significantly decreased 12 hr. after freezing; these measures had returned to prefreezing levels by 3 mo. The responses to insulin and peptone were significantly decreased 12 hr. after freezing. This response also returned to prefreeze levels in 3 mo.

- 9660 EFFECT OF PORTACAVAL SHUNT ON GASTRIC ACID SECRETION IN DOGS WITH LIVER DISEASE, PORTAL HYPERTENSION AND MASSIVE ASCITES. (E.) Orloff, M. J. (U. California Sch. Med., Los Angeles) and C. W. O. Windsor. *Ann. Surg.* 164(1):69-80, 1966.

Eighteen daily control collections of Heidenhain pouch secretion were made preceding ligation and division of all hepatic veins except the superior hepatic vein which was surrounded by a "choker". Three wk. postoperatively secretory studies were resumed and the hepatic vein "choker" periodically tightened restricting flow until massive ascites and abnormal liver function developed. Ascites was terminated by a side-side portacaval shunt. Four measures of gastric secretion were collected: 1) 24-hr. vol. and acid; 2) daily 6-hr. postcibal vol. and acid; 3) 2-hr. response to histamine (0.1 mg/kg s.c.); 4) 6-hr. response to test meal. Liver function tests were performed every 1-2 wk.; ascites was confirmed by needle paracentesis. Liver biopsies were performed twice during surgery and at sacrifice. Following hepatic vein ligation alone developed morphologic and chemical evidence of severe hepatic damage, portal hypertension and massive ascites. Portacaval shunt reduced portal pressure and relieved ascites, but hepatic abnormalities and pathology were not corrected. Following ligation, gastric secretion was significantly depressed: daily acid production, by 61%; 6-hr. postcibal acid output, by 68%; response to histamine, by 31%; acid secretion following test meal, by 74%. Portacaval shunt produced an immediate hypersecretion: daily acid production, +1619%; 6-hr. postcibal acid output, +1714%; histamine response, +345%; acid secretion to test meal, +2490% greater than control levels. Ligation of the shunt in one dog resulted in reappearance of massive ascites and gastric secretion depression.

- 9661 THE SEPARATE DETERMINATION OF HUMAN PEPSIN AND GASTRICSIN. (E.) Chian, S. (U. Oklahoma Med. Ctr., Oklahoma City), L. Sanchez-Chiang, S. Wolf and T. Tang. *Proc. Soc. Exp. Biol. Med.* 122(3):700-703, 1966.

N-Acetyl-L-phenylalanyl-L-diiodotyrosine (I) found to be hydrolyzed by human pepsin. A method not by gastricsin was used as the basis for a method for the determination of the activity of these enzymes in gastric juice. Pepsin conc. was determined spectrophotometrically from a standard curve after incubation of 1 soln. with gastric juice. Total proteolytic activity of the gastric juice was determined spectrophotometrically by a modification of the Anson-Mirsky hemoglobin substrate method. Sample calculations were given for the determination of gastricsin by subtracting the pepsin conc. from the total proteolytic activity of the gastric juice. Stimulation of gastric secretion in 9 subjects (age, sex not given) by histamine (dose not given) showed an increase in both gastricsin (from control level 0-380 to 136-520 $\mu\text{g/ml}$) and pepsin (from control levels 0-820 to 144-870 $\mu\text{g/ml}$) conc.

- 9662 RELATIONSHIP OF HISTAMINE-STIMULATED GASTRIC SECRETION TO GASTRIC BLOOD FLOW AND OXYGEN CONSUMPTION: PATTERNS OF ARTERIAL AND VENOUS RESPONSE. (E.) Domanig, E. (State U. New York, Buffalo), P. B. Hahnloser and W. G. Schramm. *Ann. Surg.* 164(1):81-89, 1966.

Twenty dogs anesthetized with chloralose breathing 50% O₂ in room air were splenectomized, the duodenum ligated and the stomach cannulated. An electromagnetic flow probe was placed on the left gastric artery. In 7 dogs a second flow probe was placed on the ascending aorta and in 14 the left common carotid artery. Gastric juice was collected at 20-min. intervals, arterial pressure was recorded from a carotid or femoral artery. In 11 dogs blood samples for determination of O₂ saturation were collected from the gastric vein and the right atrium. Histamine was infused, 1 $\mu\text{g/kg/min. i.v.}$, or 1.0 $\mu\text{g/kg/min. intra-arterially}$. Intravenous histamine produced a transient rise in gastric blood flow, increased carotid flow, and decreased arterial pressure, 15-20%. Intra-arterial histamine produced a sustained increase in gastric blood flow with no change in carotid flow or arterial pressure. Histamine (i.v.) increased carotid flow. Gastric venous O₂ saturation increased following intra-arterial histamine; i.v. histamine gastric venous O₂ fell from its normal level of 80% to near central levels of 63%. The doses of histamine required intra-arterially were 1% of the doses for equal secretory effects.

- 3 EFFECT OF CHANGES IN GASTRIC SECRETION ON PROTEIN TOLERANCE AFTER PORTACAVAL SHUNT. (E.) Peloso, O. A. (U. California Sch. Med., San Francisco), S. Jacobson and W. Silen. Am. J. Surg. 112(2):279-286, 1966.

cases are reported of portacaval shunt followed by encephalopathy; dog studies were undertaken to ascertain if changes in gastric acid secretion would affect ammonia production in an isolated jejunal segment. A 10-cm segment drained by a single vein supplied by a single artery was clamped off; in 14 dogs venous blood ammonia determinations were made before, and periodically after inj. of 5% protein hydrolysate soln. into the segment. Identical tests were performed on 8 dogs 6 wk. after pyloroplasty and partial vagotomy, 5 were given 0.35 mg histamine daily for 2 wk. and restudied. Similar studies were carried out with inj. of 5% proteose peptone into the segment, in groups of 14 and 21 dogs. Intestinal bacterial enzymes (urease and amino acid oxidase) were estimated from inj. and aspirated phosphate buffer in another intestinal segment. Following protein hydrolysate infusion blood ammonia in normal dogs rose from 2.56 to 15 $\mu\text{g/ml}$ at 8 min., then declined. In vagotomized dogs blood ammonia rose from 9 to 13 $\mu\text{g/ml}$ at 8 min. and remained elevated. Dogs vagotomized but treated with histamine were similar to controls. Following proteose peptone infusion in control dogs blood ammonia rose from 2.57 $\mu\text{g/ml}$ to 3.9 $\mu\text{g/ml}$ at 60 min., 17 of 21 vagotomized dogs showed similar results, 4 showed an increase from 3.58 to 8.96 $\mu\text{g/ml}$ and remained at this level. No significant differences between groups were shown in the data collected on intestinal bacterial enzymes. In a third clinical case a dog with mesocaval shunt following vagotomy had severe hepatic encephalopathy if more than 30 g protein/day. Acidification of the small intestine by infusion of HCl into the jejunum lowered production of ammonia after gastric-administered proteose peptone soln. and decreased urease and amino acid oxidase in the jejunum. It is suggested that achlorhydria resulting in overgrowth of intestinal flora may enhance the development of encephalopathy after portacaval shunt.

- 4 RELATIONS BETWEEN HISTOLOGICAL PATTERNS AND FUNCTIONAL DATA ON GASTRIC SECRETION. (E.) Saracco, C. (U. Turin, Italy), G. Bruno and M. De La Pierre. Panminerva Med. 8(1-2):14-18, 1966.

Gastric secretions were collected every 15 min. by aspiration following 0.5 mg histamine in 88 patients with functional digestive disorders, 53 males, 35 females, ranging in age 23-78 yr. Gastric biopsy (Wood suction biopsy tube) yielded 2 or 3 specimens per patient. Of 14 patients showing increased gastric secretion, 9 had a normal histologic pattern, and 5 had moderate cell infiltration (superficial gastritis). Of 33 patients showing normal secretory patterns, 23 had superficial gastritis, 8 had normal mucosa and 2 had moderate glandular changes. Of 25 patients having reduced gastric secretion, 1 had normal mucosa, 13 superficial gastritis, 9 had moderate glandular changes, and 2 had advanced atrophy of the mucosa. In 16 patients having no gastric acidity there were none with normal mucosa, 3 had superficial gastritis, 1 had pre-atrophic changes and 12 had atrophic gastritis. The 2 variables were found to be significantly correlated by chi-square test.

- 5 ALKALINE INORGANIC PYROPHOSPHATASE IN THE MUCOUS GLANDULAR CELLS. (E.) Fischer, E. (U. Pecs Teach. Train. Coll., Hungary). Acta Biol. Acad. Sci. Hung. 17(2):159-166, 1966.

Alkaline inorganic pyrophosphatase (APPase) activity was determined by Korhonen's method in selected tissues in the epithelium of the alimentary canal and in the glands of the integumentum commune of the: albino rat, albino mouse, edible frog, carp, bull-pout, edible snail, and the leech. It was found that APPase activity was common in glandular cells producing mucous secretion. Salivary gland cells and intestinal epithelial cells in rats and mice, some cutaneous glands of the carp and pout, snail mid-intestinal gland cells and mantle hem cells, and the albumen glands (skin) of the leech showed positive APPase activity. The endocrine and exocrine acini of the pancreas, mucous cells of the salivary glands, sebaceous glands of the mouse and rat and the intestinal cells of the snail were found to be relatively free of APPase activity.

- 6 THE CHARACTERIZATION OF RAT PANCREATIC ZYMOGENS AND THEIR ACTIVE FORMS BY GEL DIFFUSION TECHNIQUES. (E.) Pascale, J. (Inst. Sci. Cancer Res., Villejuif/Seine, France), S. Avrameas and J. Uriel. J. Biol. Chem. 241(13):3023-3027, 1966.

SECRETION

The zymogens and enzymes of rat pancreas were subjected to immunologic technics and their antigenic characteristics determined. Specific reactions with appropriate substrates were used to localize the zymogens and their active forms on the immunoelectrophoretic diagrams. Elastase α -amylase, ribonuclease, carboxypeptidase- β , chymotrypsin and lipase were identified as single antigens. Two immunologically distinct enzymes with carboxypeptidase-A activity as well as two others with trypsin activity were demonstrated. The following zymogens have been identified: one proelastase, one chymotrypsinogen, one procarboxypeptidase β and two immunologically distinct trypsinogens, the procarboxypeptidase-A as two electrophoretic fractions with common antigenic properties. Two immunologically-distinct trypsins are derived from the 2 trypsinogens. The procarboxypeptidase-A gives rise when activated to 2 immunologically distinct carboxypeptidases A.

- 9667 FURTHER INVESTIGATIONS ABOUT THE SITE OF PRODUCTION OF CASTLE'S GASTRIC INTRINSIC FACTOR. (E.) Hoedemaeker, P. J. (U. Groningen, Netherlands), J. Abels, J. J. Wachters, A. Arends and H. O. Nieweg. Lab. Invest. 15(7):1163-1173, 1966.

The regional and cellular localization of intrinsic factor in gastric mucosa was studied in: mouse, guinea pig, cat, rabbit, rhesus monkey, ox, and the hog. Extracts of the fundus and pyloric antrum, also duodenum in the hog were tested in vitro for specific B₁₂ binding power; the specific cellular uptake of vitamin B₁₂ was determined (from fresh stomach mucosa, sectioned, fixed and incubated with Co⁵⁷-B₁₂) with autoradiography. Inhibition of B₁₂ binding in the sections was accomplished by incubation with γ -globulin. In each animal species only one cell type showed B₁₂ uptake that could be blocked by γ -globulin, but there appeared to be 3 types of intrinsic factor production: 1) The human type (parietal cells) in the guinea pig, cat, rabbit, rhesus monkey and ox; 2) the rat type (chief cells) rat and mouse; 3) hog type, intrinsic factor production in glandular cells of the pyloric zone and the duodenum.

- 9668 THE PHYSIOLOGICAL EFFECTS OF SPICES AND CONDIMENTS. VII. INVESTIGATION INTO THE MECHANISM OF ACTION ON SALIVARY GLAND FUNCTION. (Ger.) Blumberger, W. (Max-Planck Inst., Dortmund, Germany) and H. Glatzel. Nutr. Dieta (Basel) 8(2):145-160, 1966.

A number of species (a list and their structures are given) were tested for their ability to stimulate salivary secretion and to influence salivary content as to conc. of mucin, neuraminic acid, and hexosamine, and as to amylase activity. It was found that in order to have any effect, the spices must have come in contact with the mucous membranes of the oral cavity, whether they are later swallowed (digested) or not. This indicates that receptors for the sialogogic spices are in the oro-naso-pharyngeal region, and are activated only by direct contact.

- 9669 GASTRIC INTRINSIC FACTOR SECRETION AFTER PARTIAL GASTRECTOMY. (E.) Ardeman, S. (St. Mary's Hosp., London) and I. Chanarin. Gut 7(3):217-219, 1966.

To determine if conc. or output of intrinsic factor in gastric juice was best correlated with absorption of B₁₂, and which was the best guide as to the amount available, observations were made on 16 patients who had undergone Polya-type partial gastric resections. Twenty had megaloblastic anemia, with iron deficiency in 11, due to iron deficiency alone in 3. None had serum intrinsic factor antibodies. Gastric juice samples were obtained by suction or aspiration 1 hr. before and after histamine, 40 μ g/kg. Intrinsic factor assay was done by Ardeman and Chanarin's method. B₁₂-absorption was assessed by Schilling's method using 1.0 μ g p.o. Co⁵⁷-vitamin B₁₂. Comparable data were collected in 68 hospital patients and 42 patients with Addisonian pernicious anemia and used for comparative purposes. Conc. of intrinsic factor in 8 gastrectomy patients was from 0-6 U/ml; B₁₂ absorption was impaired. Three patients whose anemia was felt to be due to low folic acid had normal B₁₂ levels, and low to normal intrinsic factor levels. Five patients had intrinsic factor conc. of 10-46 U/ml; all absorbed B₁₂ normally. The conc. of intrinsic factor in the gastrectomy group was in the range of the Addisonian pernicious anemia patients for those patients with impaired B₁₂ absorption, and in the normal range for those tha

CRETION

could absorb B₁₂. A good correlation was found between conc. of intrinsic factor and the results of the B₁₂ absorption test. It is concluded that determination of intrinsic factor in gastric juice could be of value in diagnosing B₁₂ deficiency.

70 EFFECT OF MONOMYCIN AND NEOMYCIN ON SECRETION AND CHEMICAL COMPOSITION OF GASTRIC JUICE IN DOGS UNDER DIFFERENT CONDITIONS OF THE CENTRAL NERVOUS SYSTEM. (Rus.) Govorovich, E. A. (Vishnevskii Inst. Surg., Moscow) and L. V. Elagina. Antibiotiki 11(7):631-637, 1966.

The effect of monomycin (M; 12,500 and 25,000 U/kg/day for 3-5 days, p.o.) and neomycin (N; 16,700 U/day for 3-5, p.o.) on the intensity of gastric secretion depended on its chemical structure depended on the state of excitation or depression of the CNS. The highest conc. of M in gastric juice of dogs was found in the first hr. after admin. and was always decreased after 3 hr. M was absent or found only in traces in the blood. M increased in both dogs with quiet (QD) and excitable dispositions (ED), the gastric juice, total acidity, total chloride, urea and ammonia, while free-acid was seldom found. N, in QD dogs, increased gastric juice, total chloride, ammonia, urea, and decreased total acidity, while in ED dogs it increased gastric juice and decreased the other indicators. Admin. of M to dogs pretreated with caffeine-Na (1 ml 10% soln., i.m.) increased all indicators in QD dogs, while in ED dogs total acidity, total chloride and ammonia were decreased. Admin. of N to QD dogs pretreated with caffeine resulted in an increase in all indicators except total acidity which was decreased, while in ED dogs gastric juice and ammonia were decreased and the other indicators increased. Admin. of M to QD dogs pretreated by Medinal (2 g, p.o.) increased all the indicators. Caffeine alone caused in QD dogs an increase in gastric juice, total chloride, ammonia and urea, and a decrease in total acidity; while in ED dogs total acidity, total chloride and urea were decreased, and gastric juice and ammonia increased. M alone given to the QD dog decreased the gastric juice, total acidity and urea, and increased total chloride and ammonia.

CYTOLOGICAL LOCALIZATION OF NORADRENALINE, MONOAMINE OXIDASE AND ACETYLCHOLINESTERASE IN SALIVARY GLANDS OF DOG. (E.) Fujiwara, M. (Kyoto U. Sch. Med., Japan), C. Tanaka, H. Hikosaka and T. Okegawa. J. Histochem. Cytochem. 14(6):483-490, 1966.

The salivary glands of the dog, the norepinephrine-fluorescent nerve fibers surrounded the secretory acini of the submaxillary, sublingual and parotid glands, but the density in the sublingual gland was much less than in the other two. Norepinephrine fluorescence was not seen in the cytoplasm of the acinar cells nor in the vicinity of the excretory ducts. In contrast, all the cells of the secretory acini and the excretory ducts were stained evenly when monoamine oxidase activity was measured. The distribution of fibers showing acetylcholinesterase activity was different from that of norepinephrine-fluorescent fibers only in that the former fibers were present around the excretory ducts as well. The cytologic localization of these three substances in dog salivary glands is essentially similar to that found in rats, despite a difference in the composition of secretory cells in the submaxillary and sublingual glands seen in these 2 species. It is concluded that the autonomic nerve supply, adrenergic as well as cholinergic, to the salivary glands are not correlated with the type of secretory cells.

72 ON THE MECHANISM OF INHIBITION OF INTESTINAL ALKALINE PHOSPHATASE BY L-PHENYLALANINE. I. KINETIC STUDIES. (E.) Ghosh, N. K. (Tufts U. Sch. Med., Boston, Mass.) and W. H. Fishman. J. Biol. Chem. 241(11):2516-2522, 1966.

Kinetic study of the inhibition of intestinal alkaline phosphatase by L-phenylalanine describes this stereospecific, organ-specific inhibition as arising from the formation of a thermodynamically stable enzyme-inhibitor-substrate complex. The inhibition was greatly dependent on substrate and inhibitor conc. and was of the competitive type. The degree of inhibition of rat intestinal alkaline phosphatase by L-phenylalanine was highly pH-dependent and varied from 0-66% within a pH range 7.8-10.4. The Michaelis constant of this reaction was also pH-dependent. The values for the energy of activation for the enzyme-catalyzed hydrolysis of phenylphosphate with and without L-phenylalanine were 18,000 and 6,000 calories/mole, resp.

SECRETION

- 9673 INHIBITORY EFFECT OF 1-ALKYLBENZIMIDAZOLES ON GASTRIC SECRETION IN THE RAT. (E.) Méhes, J. (Med. U., Pécs, Hungary), L. Decsi, M. K.-Várszegi, H. Hideg and O. H.-Hankovszky. J. Pharm. Pharmacol. 18(8):551-552, 1966.

A new series of benzimidazole derivatives are reported to have an inhibitory effect on gastric secretion. 1-(2-Piperidinoethyl)benzimidazole (I) had an ED₅₀ on gastric secretion in the rat of 10 mg/kg for free acid, 11.2 for total acid, and 16.4 for gastric juice; the method of study was not described. I increased gastric emptying time and inhibited intestinal motility at doses of 12.5-25 mg/kg i.m. and 50-100 mg p.o. I had no effect on acetylcholine-induced contractions in rat duodenum in vitro or acetylcholine-induced vasodepression in cats and dogs in vivo. Vasodepression due to cervical vagal stimulation in the cat was abolished by doses that did not influence nictitating membrane contraction due to stimulation of the superior cervical ganglion. Bradycardia and vasodepression due to thoracic vagal stimulation were abolished, while tachycardia and vasopression due to stimulation of the stellate ganglion were not. The compound does not block the pressor effect of tetramethylammonium which is blocked by tetraethylammonium. It is concluded that the new compound selectively blocks parasympathetic transmission. A similar action in the CNS is suggested by the compound's sedative action and the inhibition of carbachol rage (intrahypothalamic) in cats and excitation in rats after deoxyephedrine.

- 9674 THE ROLE OF ANTRUM-PYLORUS-DUODENUM IN GASTRIC SECRETION IN THE RAT. (E.) Dobi, S. (U. Med. Sch., Debrecen, Hungary), T. Jávör, A. Györffy and G. Mózsik. Acta Physiol. Acad. Sci. Hung. 29(3-4):334, 1965.

Ligation at the corpus-antral junction in rats produced the same acid secretion and ulcer formation as did ligation at the pylorus. Resection of the antral-pyloric area did not diminish this effect. Bilateral vagotomy in pylorus-ligated animals antagonized acid secretion and ulcer production; acid introduced into the stomach caused severe lesions. Both acid secretion and ulceration were reduced if bile was rerouted to the cecum or outside the body. Ligation of the duodenum below the papilla produced similar effects. It is concluded that pylorus ligation by preventing acid from entering the duodenum provokes a hypersecretion due to the action of alkaline bile and pancreatic juice acting on the intestinal mucosa. This hypersecretion requires intact vagi. Neither the antrum, pylorus, or gastrin play a role in this hypersecretion which leads to ulcer production.

- 9675 DIFFERENCES IN GASTRIC ACID OUTPUT IN RESPONSE TO HISTAMINE BETWEEN MALE AND FEMALE GUINEA PIGS. (E.) Voith, K. (McGill U., Montreal, Canada) and B. A. Kovacs. Canad. J. Physiol. Pharmacol. 44(4):515-520, 1966.

After ligation of the duodenum approx. 2 cm from the pylorus a polyethylene tube was inserted 2-3 mm into the stomach of guinea pigs through an incision 1 cm proximal to the pylorus. The stomach was then washed by inj. of saline p.o. Gastric secretions were collected at 15-min. intervals by washing in similar fashion with 3 ml of water. Histamine was admin. at doses ranging from 0.1-1.2 mg/kg s.c. In studies with 32 male and 50 female guinea pigs 0.1 mg histamine/kg produced equal results in the 2 sexes. After 0.2 mg/kg both vol. and acidity were higher in the male animals. 0.4 mg/kg produced max. secretion in both groups; both vol. and acid levels were higher in the males. Histamine (0.8 or 1.2 mg/kg s.c.; supra max. dose) produced similar effects. It is concluded that there is a basic difference in acid secretory ability between male and female guinea pigs under max. histamine stimulation.

- 9676 A METHOD FOR THE CONTINUOUS MEASUREMENT OF NET IONIC FLUXES IN GASTRIC POUCHES. (E.) Wlodek, G. K. (Montreal Gen. Hosp., Canada) and R. K. Leach. Canad. J. Surg. 9(3):237-241, 1966.

After preliminary experiments showed polyethylene glycol (PEG) was not absorbed in vivo (Heidenhain pouch) or modified in vitro (incubation in gastric juice and mucus) it was selected as a marker substance, i.e. 10 mg/ml soln. of 100 mEq HCl, NaCl 15 mEq/liter and 0.078 N mannitol. Fifty ml of this soln. was introduced into watertight Heidenhain pouches and retained for 30 min. Five ml of soln. was then introduced into the pouch and thoroughly mixed and a 5 ml aliquot removed. Such

CRETION

samples were taken at 30-min. intervals for 6 hr. Food, histamine or insulin was min., usually after 90-150 min. The samples were analyzed for PEG conc., Na conc., and Cl^- . In 71 four-hr. experiments total av. recovery of PEG was 99.9%. The data for 7 experiments with histamine in 1 dog showed basal secretion was 0.9-0.5 ml/30 min., H^+ flux varied from 94-130 μM . After histamine inj. (0.5 mg/kg s.c.) H^+ increased to 12.7 ml/30 min., H^+ flux increased to 886-2035, Na^+ decreased, histamine, Cl^- and K^+ were increased. It is concluded that PEG is an ideal marker for use in such studies.

- 77 THE MECHANISM OF GASTRIC HYPERSECRETION FOLLOWING PANCREATIC DUCT LIGATION. (E.) Kyle, K. F. (Queen's U., Belfast, Northern Ireland) and R. B. Welbourn. *Brit. J. Surg.* 53(4):380-384, 1966.

The effects of normal and atrophic pancreas extracts, feeding and ligation of the pancreatic ducts were studied in dogs prepared with Heidenhain pouches. Secretions were collected for 4 hr. after 18 hr. of fasting. The extracts of atrophic pancreas from dogs undergoing pancreatic ligation did not stimulate secretion, nor did blood glucose fall following s.c. admin. Of 12 dogs surviving pancreatic duct ligation for 3 mo. (daily feedings of pancreatic enzyme, Cotazym) duodenal ulceration was present in 5. Basal secretion (24 hr.) was unchanged after pancreatic duct ligation, but there was an increase of 188% in free acid secretion. Substitution therapy with Cotazym did not prevent hypersecretion. The addition of pancreatic juice from donor dogs caused a fall in secretion of acid. Olive oil feeding in intact pancreas dogs inhibited free acid in the pouch. After duct ligation olive oil failed to inhibit acid secretion. Olive oil plus pancreatic juice feeding resulted in acid inhibition. After duct ligation was followed by increased serum and bile lipase levels which slowly fell until subnormal levels were reached in 5 wk.; in no case did hypersecretion occur until blood-lipase had fallen to normal levels. It is suggested that duct ligation results in hypersecretion by interfering with the normally inhibitory effect of fat. It remains unclear how fat exerts its inhibitory effect on gastric secretion.

- 78 INFRA-RED SPECTROSCOPIC INVESTIGATIONS OF A NEW ACID MUCOPOLYSACCHARIDE ISOLATED FROM HUMAN GASTRIC JUICE. (E.) Terho, T. (U. Turku, Finland), K. Hartiala and I. Hakkinen. *Nature (London)* 211(5045):198-199, 1966.

In canine gastric wall in addition to hyaluronic acid and chondroitin sulfates, traces of a sulfated mucopolysaccharide were found. To investigate this constituent identified with mucus secretion, human gastric juice was collected and the acid mucopolysaccharides precipitated with cetylpyridinium chloride after hydrolysis with papain. Four fractions soluble in 0.3 N NaCl and in 0.5, 0.6, and 0.8 N MgCl₂, resp., were studied and found to contain fucose, galactose, glucosamine, lactosamine, sialic acid and sulfate, but no hexuronic acids. The molar ratios of the monosaccharide components were comparable for all fractions; the degree of sulfation increased from the 0.3 fraction through the 0.8 fraction. Infrared spectra were similar except in the sulfate absorption band. The spectra were very similar to those of hyaluronic acid and chondroitin sulfates. It is concluded that the fractions represent various sulfation grades of the same polysaccharide.

- 79 SALIVATION AND INSTRUMENTAL RESPONDING TO AN INSTRUMENTAL CS PRETRAINED USING THE CLASSICAL CONDITIONING PARADIGM. (E.) Ellison, G. D. (Nencki Inst. Exp. Biol., Warsaw, Poland) and J. Konorski. *Acta Biol. Exp. (Warsz.)* 26(2):159-165, 1966.

A strong conditioned salivary response was trained in 3 dogs by pairing a conditioned stimulus (CS_1) with food presentations (US) for 200 trials. The CS_1 -US interval was lengthened from 2-10 seconds. An instrumental response, paw lifting or lever pressing, was then trained to a new stimulus (CS_2) by presenting food only when and if the response occurred during CS_2 for 100 trials. CS_1 (salivary response) and CS_2 (instrumental response) trials then were alternated with the instrumental reinforcement contingency applied to both CS_1 and CS_2 . Four presentations a day of each CS were given for 200 trials. Considering only these final 200 trials, it was found that although salivation occurred to both CS_1 and CS_2 , conditioned salivation was always greater to CS_1 and instrumental conditioning was

SECRETION

always greater to CS₂. It is concluded that the data substantiate a separation of the drive conditioned response and the consummatory conditioned response.

- 9680 EFFECTS OF TREATMENT WITH ISOPRENALINE OR PILOCARPINE ON THE SECRETORY RESPONSES OF THE PARASYMPATHETICALLY DENERVATED SUBMAXILLARY GLAND OF THE RAT. (E.) Ohlin, P. (U. Lund, Sweden). J. Oral Ther. 2(5):376-379, 1966.

The right chordal lingual nerve was sectioned in 4-5 mo. female rats 12 days preceding isoprenaline 7.5 mg twice daily or pilocarpine 10 mg twice daily i.p. for 1 wk. Secretory responses were measured by cannulation of the submaxillary duct. Dry wt. of denervated glands increased after isoprenaline; pilocarpine had no effect. Secretory threshold doses in denervated glands of acetylcholine, methacholine and epinephrine after isoprenaline were not different from those for denervated glands in untreated rats. When expressed per gland the max. secretory response to pilocarpine was not significantly changed; when expressed per unit wt. the response was decreased. The sensitivity of denervated glands to secretory drugs was lowered after pilocarpine treatment. The response to pilocarpine was found to be unchanged (See no. 9679)

- 9681 EFFECTS OF ATROPINE TREATMENT ON THE SUBMAXILLARY GLAND OF RATS. (E.) Ohlin, P. (U. Lund, Sweden) and C. Perec. Quart. J. Exp. Physiol. 51(3):196-201, 1966.

The salivary glands of rats were studied after 1 and 7 days of treatment. For 1 day five groups were used: atropine, 2 doses (50 mg/kg 12 hr. apart) and section of chordal lingual nerve; pilocarpine, 2 doses (50 mg/kg 12 hr. apart) and section of chordal lingual nerve; section of chordal lingual nerve only; controls. For 7 days 4 groups were used: atropine (10 mg/kg twice daily for 4 days to 50 mg/kg twice daily for 3 days); same doses of atropine plus section of the chordal lingual nerve; section of nerve only; controls. Secretory responses were determined during anesthesia after cannulation of secretory ducts following epinephrine 0.1-20 µg/kg and isoprenaline 0.01-100 µg/kg i.v. Succinic dehydrogenase was manometrically estimated (Warburg technic); fumarase was determined spectrophotometrically. Atropine for one day increased submaxillary net wt. 7%, dry wt. 8%; 1 wk. of atropine decreased net and dry wt. The decrease in gland wt. at 1 wk. was paralleled by decreased body wt. Pilocarpine decreased gland wt. Denervated glands were heavier after 1 day; after a wk. denervated glands had decreased in wt. Atropine, 1 day, blocked gain in denervated glands; atropine for 7 days did not affect wt. One wk. of atropine or denervation produced a 10-fold increase in sensitivity to the secretory effects of epinephrine and isoprenaline. Total activity and conc. of the enzymes studied were decreased following 1 wk. of atropine or denervation. (See no. 9682)

- 9682 DISTURBANCES OF GASTRIC JUICE. XI. MEASUREMENT OF THE ELECTRICAL RESISTANCE OF GASTRIC JUICE IN THE DOG. (Fr.) Bernier, J. J. (Paul-Brousse Hosp., Villejuif, Seine, France), A. Monsaingeon and P. Tanret. Rev. Franc. Etud. Clin. Biol. 11(5):524-531, 1966.

Quantitative analyses were made on 68 samples of gastric juice obtained from dogs (some stimulated by histamine) for conc. of H⁺, Cl⁻, Na⁺, and K⁺ expressed as mEq/liter. The mEq/liter of these ions were added to obtain the total ionic conc. of each sample; these 4 ions actually comprise 98% of the total ions in the secretion. The resistance in ohms cm/cm² was measured by a Philips bridge for each gastric juice. The total ionic conc. of gastric juice is expressed in terms of resistance in ohms, or, the reciprocal of ohms, $\frac{1}{R}$ (multiplied by 10⁴ for convenience of dealing with whole numbers). The resistance is easily obtained requiring only one measurement. The graph of $\frac{1}{R}$ on the ordinate against the total ionic conc. in mEq/liter on the abscissa shows $\frac{1}{R}$ a rectilinear relationship with a sharp decrease in slope at the point where the secretion changes from acidic to achlorhydric. The use of resistance to obtain the total ionic conc. is facilitated by reference to curves derived from mixtures of two soln. which simulate gastric juices of different ionic composition. The numerical values for each substance are given mM/liter. For gastric juices of the dog the soln. are: 155 HCl plus 7 KCl; and 106 NaCl plus 7 KCl plus 30 NaHCO₃. For human gastric juices the soln. are: 143 HCl plus 22 KCl; and, 70 NaCl plus 22 KCl plus 20 NaHCO₃.

CRETION

- 83 THE ELECTROLYTES OF GASTRIC JUICE. (Fr.) Vagne, M. (Edouard-Herriot Hosp., Lyon, France), F. Martin, A. Berard and R. Lambert. Rev. Franc. Etud. Clin. Biol. 11(5):493-509, 1966.

Variations in electrolytes in human gastric juice were studied in gastric secretions, contaminated by saliva, obtained before and after stimulation following rejection of gastric juice initially present in the fasting stomach. Samples were taken over 3-hr. period; in the first hour four 15-min. samples were obtained of the resting secretion to establish basic values; after inj. of stimulant eight 15-min. samples were obtained from each subject. Secretory samples were taken from 38 subjects: 10 inj. s.c. with 0.5 mg histamine as stimulant, from 21 persons inj. i.v. with 0.5 U of insulin, and from 9 individuals inj. i.v. with 1.25 mg reserpine in 10 ml of 0.9% NaCl medium. Measurements were made of free and total acidity and conc. of Cl, K, Na, Ca and Mg ions. Studies of the acid and ionic conc. showed that there are 2 groups of electrolytes quite different in behavior. Group 1 consists of Cl, Na and Ca. The variations in Cl conc. follow closely those of gastric acidity, whereas Na and Ca ions have an inverse relationship to acidity. Group 2 includes K and Mg ions which have no marked relationship to acidity or to the ions of Group 1. Under stimulation the conc. of K and Mg rises sharply, then falls to a level somewhat below the beginning value. The rise is very early and precedes that of the acid conc. which explains the lack of correlation. The rise in Mg ion seems to occur earlier than that of K ion. It is suggested that these ions are concerned in the initiation of gastric secretion. A study of the output of each electrolyte indicates that chloride varies in the same way as the acid output. Na output rises rapidly in the first sample under stimulation, possibly due to a process of washing out. In the following samples Na is released less than in the corresponding periods of resting secretion representing a decrease in primary alkaline secretion under histamine stimulation. Variations in Ca ion follow those of Na. Histamine first increases the output of K and Mg followed by a fall in the output below the values found in spontaneous secretion.

- 84 A MODIFICATION OF THE HUNT METHOD FOR ESTIMATING PEPTIC ACTIVITY IN GASTRIC JUICE. (E.) Bitsch, V. (Bispebjerg Hosp., Copenhagen, Denmark). Scand. J. Clin. Lab. Invest. 18(13):357-358, 1966.

The Hunt method for estimation of peptic activity in gastric juice was modified in several respects. Gastric juice is diluted with an equal vol. of HCl, pH 1.9. A 5 ml sample is added to 2.5 ml substrate soln. (56 g bovine citrated plasma/liter) after heating to 37° C. After 15 min., 5 ml of 0.35 N trichloroacetic acid is added to arrest the reaction. After 4 min. at 37° C samples are filtered (Munktell filters 0.00). Five-hundred μ l filtrate are added to 10 ml 0.25 N NaOH to which 1 ml diluted Folin-Ciocalteu's phenol reagent is added. The resulting blue color is read after 5 min., but before 30 min. at 680 m μ moles in a Beckman spectrophotometer. A calibration curve was drawn on the data collected on 9 soln. of 0-1250 mg/liter crystalline pepsin. A new calibration curve is drawn each time a batch of plasma or reagent is used. The differences between curves until now have been slight. Reproducibility of the method (duplicate analyses) has been excellent.

- 85 INHIBITION OF GASTRIC SECRETION BY FRACTIONATED LYMPH ELABORATION OF GASTRONE-LIKE SUBSTANCE DURING DIGESTIVE PHASES IN DOGS. (E.) Rudick, J. (U. Washington Sch. Med., Seattle), A. K. Gajewski, C. L. Pitts, L. S. Semb, T. L. Fletcher, H. N. Harkins and L. M. Nyhus. Am. Surg. 32(8):513-520, 1966.

Five dogs were prepared with Heidenhain pouches; 2-3 wk. postoperatively the thoracic pouch was cannulated both cranially and caudally, provisions being made to connect the cannula extracutaneously with the tip of the distal cannula within the cysterna pylori. The 2 cannulae were disconnected only during test. Lymph collections were made every 2-4 hr. after 18 hr. fasting, after a beef liver meal, and after a milk-cream oil meal. After stirring for 1 hr. with 5 vol. of chloroform-methanol (2:1 v/vol.) the soln. was centrifuged. Three fractions emerged: 1, aqueous at top, intermediate white, 3, clear lipid-chloroform layer at bottom. Fractions 1 and 3 were dried, redissolved in water, dialyzed and lyophilized; 2 was washed in ether, dried, dissolved in NaOH pH adjusted, dialyzed and lyophilized. Dogs were tested

SECRETION

after 18-hr. fast, basal secretion was recorded for 30 min., secretion was stimulated by gastrin or histamine infusion. After secretory rates were established fractions were infused i.v. (1/4 collection) over 30 min. Fractions inhibiting histamine-induced secretion were tested against gastrin (1-4 mg/hr.). Gastric juice was collected each 30 min. Fasting Lymph Fraction 1 did not affect gastric secretion. Fraction 2 reduced acid output 62.4%. Fraction 3 produced equivocal stimulation. Post-liver-meal-lymph Fraction 1 and 2 had no effect, 3 produced feeble stimulation. Post-eat-meal-lymph fractions were similar to the post-liver meal fractions. There was no difference in any of the 0-2 or 2-4 hr. lymph fractions. Fasting lymph Fraction 2 reduced gastrin-stimulated secretion 72.4%. All fractions were free of histamine. The inhibitor Fraction 2 was also found to be free of secretin, pancreozymin and cholecystokinin activities. A reduction in the fasting Lymph Fraction 2 dose of 75% still resulted in gastric inhibition. The pattern of inhibition resembled "gastric inhibitor substance" (gastrone). Purified material was more active. Identification of the substance has not yet been achieved.

- 9686 ELECTROLYTES IN GASTRIC JUICE OF MAN. I. A STATISTICAL ANALYSIS OF CALCIUM AND INORGANIC PHOSPHORUS BEFORE AND AFTER SUBCUTANEOUS INJECTION OF LARGE DOSES OF HISTAMINE. (E.) Burhol, P. G. (Ullevål Hosp., Oslo, Norway), J. Myren and O. P. Foss. Scand. J. Clin. Invest. 18(13):325-330, 1966.

Gastric secretions were collected by Levine tube for 1 hr. before and after s.c. inj. of 0.05 mg/kg histamine (plus 50 mg Mepyramine) in 60 patients with a variety of diagnoses including gastric and duodenal ulcer, gastritis, dyspepsia, cancer of the stomach and diarrhea. Ages ranged from 21-90 yr.; both men and women were included. The av. conc. of Ca in unstimulated gastric juice was 1/3 that of serum; the conc. of P was approx. the same suggesting a different secretory mechanism. Ca and K, P and K, and Ca and P were positively correlated before histamine stimulation. After histamine, conc. Ca and P decreased, outputs remaining constant. Ca and total HCl, Ca and vol. rate, P and total HCl were negatively correlated. Ca and Na, P and Na, and Ca and P were positively correlated after histamine. It is suggested that Ca and P belong to the non-parietal cell secretion of the gastric juice following histamine. The clear differences found in gastric juice before and after histamine secretion was suggested to indicate that the secretory mechanism changes after histamine inj.

- 9687 ELECTROLYTES IN GASTRIC JUICE OF MAN. II. A STATISTICAL ANALYSIS OF MAGNESIUM BEFORE AND AFTER SUBCUTANEOUS INJECTION OF LARGE DOSES OF HISTAMINE. (E.) Burhol, P. G. (Ullevål Hosp., Oslo, Norway), J. Myren and O. P. Foss. Scand. J. Clin. Lab. Invest. 18(13):331-334, 1966.

Gastric secretions were collected for 1 hr. before and after histamine (0.05 mg/kg) in 65 patients, av. 57.5 yr. of age. Both men and women of a variety of diagnoses were studied. The av. conc. of Mg (0.9 mEq/liter) in unstimulated gastric juice was less than that found in serum. A positive correlation was observed between Mg and Na. No correlation was found between Mg and total acid, Mg and Ca, or between Mg and P either before or after histamine. These observations were considered to suggest dissimilarities in the secretory mechanisms of Mg and Na, Mg and Ca, and Mg and P. Definite conclusions were not drawn concerning the gastric secretion of Mg.

- 9688 PROTEIN AND TOTAL NITROGEN IN GASTRIC JUICE OF MAN BEFORE AND AFTER SUBCUTANEOUS INJECTION OF LARGE DOSES OF HISTAMINE. I. A CORRELATION TO THE VOLUME RATE AND TOTAL HCl. (E.) Burhol, P. G. (Ullevål Hosp., Oslo, Norway), J. Myren and O. P. Foss. Scand. J. Clin. Lab. Invest. 18(13):335-338, 1966.

The content of total nitrogen (TN) and protein in gastric juice was determined before and after s.c. inj. histamine (0.05 mg/kg plus 50 mg Mepyramine). Gastric juice was collected 1 hr. before and after histamine in 60 patients of varying diagnoses. Vol. and total HCl (TA) were estimated in all patients, protein and TN were determined in 36 and 41 patients resp. TN was estimated by the Kjeldahl method and protein by Goa's method. Blood urea conc. was examined in 35 patients, all but

CRETION

having less than 65 mg/100 ml. The protein-nitrogen accounted for approx. 2% TN conc. before, and 9% after histamine. A possible explanation was a rapid degradation of the proteins before collection. No correlation was obtained between the values of the undegraded proteins and those of TA and vol.; a positive correlation was found between the output of TN and output of TA and between the output of TA and vol. It is concluded that TN is a more reliable indicator of proteins secreted or lost with the gastric juice than the determination of the proteins themselves.

89 PROTEIN AND TOTAL NITROGEN IN GASTRIC JUICE OF MAN BEFORE AND AFTER SUBCUTANEOUS INJECTION OF LARGE DOSES OF HISTAMINE. II. A CORRELATION TO POTASSIUM, SODIUM, CALCIUM, AND INORGANIC PHOSPHORUS. (E.) Burhol, P. G. (Ullevål Hosp., Oslo, Norway) and O. P. Foss. Scand. J. Clin. Lab. Invest. 18(13):339-342, 1966.

Gastric secretions were collected for 1 hr. before and after s.c. inj. of 0.05/kg histamine (plus 50 mg Mepyramine) in 60 patients suffering from a variety of diseases of the gastrointestinal tract. The amount of protein and output of protein were poorly correlated with conc. and outputs of the electrolytes examined both before and after histamine admin. There was also no correlation between protein and total HCl, protein and vol. A positive correlation was found between protein and Na both before and after histamine, and between protein and P after histamine. Total nitrogen (TN) and Na were positively correlated during both collections as were TN and Ca, output TN and output of Na. It is concluded that the poor correlations between protein and electrolytes in contrast to the correlations between TN and electrolytes may be the result of pepsin-induced degradation of protein. Determination of TN gives reliable information on the proteins secreted or lost with the gastric juice; Na and Ca may reflect this secretion or loss.

90 STUDY OF THE VARIATIONS OF GASTRIC ACIDITY IN THE HEALTHY BABY AFTER ADMINISTRATION OF VARIOUS TYPES OF MILK. PRELIMINARY NOTE. (It.) Brughera, F. (Prov. Inst. Child Welfare, Milan, Italy) and M. P. Cantele. Minerva Pediat. 18(3):140-143, 1966.

Four-week-old infants were fed mother's milk, partially skimmed cow's milk with a 4% protein content of the dry residue, a 20% protein, partially skimmed milk, 20% protein, partially skimmed milk with added gastric mucin and a 30.8% protein acidified powder milk. In one feeding a base was added to the sample milk. Probe samples of the stomach contents were taken 30, 60, 120, and 180 min. after feeding and pH values measured. Variations in pH from individual to individual did not correspond to variations between mother's milk and the other types. Protein content did not affect pH. The human milk and the non-acidified type decreased the gastric pH during the first 2 hr. after feeding. Values at the end of the 2 hr. fell to between 6.5 and 5 and were around 4.5 and 2 after 3 hr. The pH of acidified powdered milk varied less, remaining around 4.5. Statistical studies were made on the results.

91 EVALUATION OF PANCREATIC FUNCTION BY STIMULATION WITH SECRETIN AND PANCREOZYMIN. (It.) Comoli, G. (Maggiore Hosp., Novara, Italy), S. Maduli and G. C. Allegra. Gior. Clin. Med. 47(3):241-257, 1966.

Eight normal fasted subjects (20-70-yr. old) received i.v. inj. of secretin (1 U/kg) followed an hr. later by i.v. inj. of pancreozymin (1.5 U/kg body wt.). Duodenal contents were collected before and after stimulation together with serum samples for enzymatic analysis. The total vol./body wt. reached its max. 30 min. after secretin stimulation and 10 min. after pancreozymin stimulation. After secretin inj. 1.88 ml/kg body wt. of duodenal juice was collected compared with 1.18 ml/kg body wt. after pancreozymin stimulation. Amylase activity measured by the drometric method of Caroway was stimulated more by secretin than by pancreozymin (988 g and 1313 g of starch hydrolyzed, resp.). Serum lipase activity as measured by the Tietz method was 5 times higher 25 min. after secretin stimulation. Bicarbonate conc. increased and reached its max. value (80-90 mEq) corresponding to x. vol. values. The higher bicarbonate values after secretin stimulation might be due to increased bile. Bilirubin value increased significantly 10-20 min. after

SECRETION

pancreozymin stimulation. Leucine aminopeptidase activity (measured by the Goldberger technique) increased 0-10 min. and 20-30 min. after secretin admin. The value of these clinical studies in evaluating pancreatic function is discussed.

- 9692 CARBONIC ANHYDRASE ACTIVITY IN SALIVA IN MAN. (E.) Szabo, I. (Western Infirm., Glasgow, Scotland) and R. McG. Harden. Quart. J. Exp. Physiol. 51(3):202-206, 1966.

With human parotid saliva the carbonic anhydrase activity was related to salivary flow rate, rising from less than 1.6 K/ml at low flow rates to a max. of about 2.2 K/ml at higher rates of flow. Up to flow rates of 0.80 ml/min. there was a straight line relationship between flow rate and enzyme conc. At rates greater than 0.80 ml/min. the enzyme conc. remained constant. Thus, any study of carbonic anhydrase activity in saliva should be done with samples collected at flow rate greater than 0.8 ml/min. in order to eliminate the influence of flow rate on enzyme conc. The conc. of carbonic anhydrase in human submandibular saliva tended to be less than that in parotid saliva. The enzyme activity in the blood was greater than that found in resting saliva, but less than that found in saliva collected after stimulation. Enzyme activity was not affected by storage at 0° C, 37° C and room temperature for up to 48 hr. Similar values were found when saliva was collected with or without oil.

- 9693 PHOSPHOLIPID INVOLVEMENT IN GASTRIC MICROSOMAL ATPase. (E.) Forte, J. G. (U. California, Berkeley), G. M. Forte and R. F. Bils. Exp. Cell Res. 42(3):662-672, 1966.

Phospholipase C markedly reduced the ATPase activity of microsomes isolated from gastric mucosa of rabbit or bullfrog, whereas phospholipase D or A, lipase, neuraminidase and phosphodiesterase had no effect. This pretreatment with phospholipase C caused the ATPase enzyme to remain in the particulate fraction rather than being released into the supernatant. Electron microscopic observations revealed that after this treatment with phospholipase C, a structural degradation of the gastric microsomal membranes occurred: the formerly smooth surfaces became rough and irregular. When exogenous lecithin was added to phospholipase C-treated microsomes, a large fraction of the ATPase activity in the microsomes was restored. No such effect occurred with the addition of cephalin. Extraction of the microsomal membranes with ether removed only the more neutral lipids and did not alter ATPase activity.

DIGESTION

- 0 MULTIPLE ATTACK BY α -AMYLASES. (E.) Abdullah, M. (Iowa State U., Ames), D. French and J. F. Robyt. *Arch. Biochem.* 114(3):595-598, 1966.

multiple attack of cycloocta-amylose by α -amylase is demonstrated: Pure crystalline cycloocta-amylose treated with crystalline porcine-pancreatic α -amylase either with a 60-fold excess of crystalline sweet-potato β -amylase. After various intervals, samples of reaction mixture were withdrawn and subjected to chromatographic analysis. Controls were run by replacing the cycloocta-amylose with amylose or pure maltotriose. With cycloocta-amylose there was substantial reduction of maltotriose and glucose, while with maltotriose, the reaction was rapid and only a trace of glucose was produced. The formation of maltotriose in an enzyme system consisting of both α - and β -amylases indicated that when the α -amylase opened the cycloocta-amylose ring to form maltotriose, the latter remained complexed with the α -amylase and underwent multiple attack to form maltotriose. A similar experiment utilizing *Aspergillus oryzae* α -amylase instead of α -amylase produced complete conversion to maltose showing little, if any, multiple attack.

- 1 EFFECT OF AUTONOMIC AGENTS ON AMYLASE ACTIVITY OF RAT SUBMAXILLARY GLAND. (E.) Kridakorn, O. (U. Alabama Med. Ctr., Birmingham). *J. Oral. Ther.* 2(5):362-366, 1966.

submaxillary gland was removed for control purposes from fasted anesthetized rats 30 min. before admin. of autonomic agents. The second gland was removed at the end of the experiment. Blood samples were taken at the end of the experiment. Amylase activity was determined using the method of Myers et al. (1944). Epinephrine, 100 μ g i.p./30 min. for 2.5-4 hr., did not affect plasma amylase levels. Amylase activity of the stimulated glands doubled over control glands, norepinephrine produced no gland changes. Parotid glands showed no changes in amylase activity following epinephrine. Neither phenoxybenzamine, 1.5 mg/rat i.v., nor dichloroproteronol, 1 mg/rat/30 min. i.v., affected gland amylase levels, nor did they block epinephrine enhancement of amylase levels. Concurrent inj. of atropine (total dose 40 mg/rat) blocked amylase increases following admin. of epinephrine. It is concluded that the precise locus of action of epinephrine remains to be determined.

- 2 ISOLATION OF PURE α -AMYLASE FROM HUMAN SALIVA. (E.) Shainkin, R. (Hebrew U., Rehovoth, Israel) and Y. Birk. *Biochim. Biophys. Acta* 122(1):153-156, 1966.

procedure is described for the isolation of pure α -amylase from human saliva. Human saliva was first submitted to gel filtration on a Sephadex G-25 column, eluted by water. Approx. 90% of the protein emerged in 2 peaks; almost all the catalytic activity, assayed by Bernfeld's method, was in the first peak (tubes 40-50). This was fractionated on a DEAE-cellulose column, elution with 0.005 M ammonium acetate followed by 0.1 M and 0.2 M. This material was assayed and contents of tubes 63-76 (peak) dialyzed and again subjected to chromatography on a DE-cellulose column with 0.03 M ammonium acetate. The material was found to be chromatographically pure, the contents of the active peak tubes 62-72 were pooled, lyophilized, and freeze-dried, or kept as a conc. soln. The homogeneity of the final preparation was substantiated by: measurement of sedimentation velocity and paper electrophoresis. The activity was about 2 times earlier reported preparations; the yield was found to be 59%.

- 3 STUDIES ON THE DYNAMICS OF PEPSINOGEN DISTRIBUTION. (E.) Spender, R. P. (Yale U. Sch. Med., New Haven, Conn.), H. Stern and W. R. Thayer, Jr. *Yale J. Biol. Med.* 38(5):417-430, 1966.

method of calculating the rate constants for the distribution of alimentary canal components that enter the blood is described and illustrated by initial data on pepsinogen in 2 dogs and 2 monkeys. The half-time for disappearance of blood pepsinogen and the decay constant were calculated from values for total pepsinogen activity in multiple blood samples taken before and after total gastrectomy. The half-time was under 30 min. in monkeys and 4 hr. in dogs. From the pepsinogen content of the stomach (determined from 1:1000 dilutions of the homogenized resected

DIGESTION

stomachs), the total blood pepsinogen (preoperative conc. multiplied by the blood vol.), and the decay constant, a constant for the entry of pepsinogen into the blood, was calculated according to a formula derived in the paper. The disappearance from the blood of hog pepsinogen, infused into one gastrectomized monkey to produce a 5,600-times greater-than-normal blood conc., was characterized by a 2-part curve, the half-time of the first part corresponding to that of the endogenous pepsinogen (36 min.), while that of the second part was much longer (14 hr.). Although 2 or more decay constants are involved, the first is dominant over the others. Initial data collected from 5 patients after gastric freezing gave a half-time on the order of days for man. An analog computer model of pepsinogen production and destruction is presented and used to illustrate the effects of varying the rate constants. Possible uses of this approach in the study of the kinetics of other blood-borne substances are pointed out.

- 9704 LABELLED CHROMIUM SESQUIOXIDE AS A MARKER FOR DIGESTA: PREPARATION AND QUANTITATIVE DETERMINATION IN FAECES. (E.) Sassoon, H. F. (U. Bristol, England). *Int. J. Appl. Radiat.* 17(6):329-334, 1966.

Pigs and sheep in metabolism cages were given chromium sesquioxide (I) powder part standardized by cyclone elutriation. Aggregating tendency of I was reduced by tritiation with lactose; labeling was with Cr⁵¹. Animals were dosed twice daily with 8.33.3 mg in capsules or in the feed. Feces were collected and counted as a slurry, totally, or "grab" samples were taken. Two 100-second counting periods for each sample were done. The slurry method gave 95-97% of the direct method counts. Mean recovery of 8 single doses of 100 mg in 4 pigs was 100.12%. Dosage by capsule or in feed were found to agree closely. It is concluded that twice daily doses appeared to become as evenly dispersed as diurnal physiologic fluctuations would permit.

- 9705 IONIC CONSTITUENTS AND OSMOLALITY OF GASTRIC AND SMALL-INTESTINAL FLUIDS AFTER EATING. (E.) Fordtran, J. S. (U. Texas Southwest. Sch. Med., Dallas) and T. W. Locklear. *Am. J. Dig. Dis.* 11(7):503-521, 1966.

The electrolyte composition and osmolality of gastric and small intestinal contents were determined in 17 normal subjects fed standardized diets, some of which containing polyethylene glycol as vol. indicator. Gastric samples were taken from 5 individuals at 30 and 90 min., and from 1 subject at 30, 60, 90 and 120 min. In 11 individuals (total 28 studies), small intestinal samples were taken at descending levels at 0.5-hr. intervals. Samples were analyzed for 1) osmolality, 2) Na, 3) K, 4) Cl, 5) Ca, 6) bile salts, 7) polyethylene glycol and 8) pH. Osmotic pressure was practically unchanged in the stomach even when osmolality was much higher or lower than that of plasma. Osmotic adjustment occurred in proximal small intestine through bulk flow of water in either direction as required to equal plasma osmotic pressure. Na rose to plasma levels in mid-jejunum. At least 24 mEq of K passed through the proximal small intestine, while only 1.5 mEq arrived in the terminal ileum. Chloride rose first to plasma values in proximal jejunum, then exceeded the plasma conc. and fell to plasma conc. In the lower intestine its conc. varied wide but was always less than 100 mEq/liter. The conc. of Ca did not rise as intestinal vol. decreased progressively. Bile salts were very variable in conc. probably due to relative absorption of solute and solvent. Polyethylene glycol increased in conc. reflecting a decreasing vol. (only 1/6 in lower ileum). The pH rose along the small intestine. In the lower portion, the pH varied from 6.8-7.8. The generally basic value is probably due to increased bicarbonate ion.

- 9706 STRUCTURAL SPECIFICITY OF α -CHYMOTRYPSIN: POLYPEPTIDE SUBSTRATES. (E.) Neil, G. L. (California Inst. Techn., Pasadena) and C. Niemann. *Nature (London)* 210(5039):903-907, 1966.

Analysis of data in the literature from numerous experiments on hydrolysis of 9 peptides and proteins with completely-determined amino-acid sequences and involving 910 amino-acid residues showed that 16 of the 20 naturally-occurring amino acids were involved in hydrolysis by α -chymotrypsin. The enzyme hydrolyzed 72% of 171 residues designated Group I (tryptophan, tyrosine, phenylalanine, leucine, and methionine) and 8% of 558 Group II (12 amino-acids) residues. Methionine was

ESTION

cluded in both groups. Primary specificity was thought to be dominant in Group I, and secondary specificity in that of Group II. A comparison of the peptide hydrolysis data with kinetic data on N-acylated-L-amino-acid esters indicates that the primary specificity pattern for polypeptides is a direct reflection of that observed for the model compounds. Analysis of the max. number of possible cleavages in the CO₂ and NH₂ positions of Group I, Group II, and Group -I (47 'non-cleavages' of Group I) resulted in the conclusion that location at the N-terminal or penultimate to the C-terminal end of a peptide chain appears to be a major reason for lack of hydrolysis of a normally susceptible (Group I) residue. The results of comparison of the number of times each residue was found in the NH₂ position of a peptide bond which involved as the carboxyl end one of the amino-acids of Group I, II, or -I with the expected frequency of the residue in that position suggest that, in the NH₂ position, alanine, glycine, and lysine favor hydrolysis, whereas aspartic acid, proline, and histidine tend to prevent it. A similar study of the CO₂ position suggests that lysine, valine, and possibly isoleucine act favorably, while aspartic acid, asparagine, histidine, and serine hinder hydrolysis.

7 PROTEINS OF THE SUCCUS ENTERICUS FROM THE JEJUNUM OF THE SHEEP. (E.)

McDougall, E. I. (Rowett Res. Inst., Bucksburn, Aberdeen, Scotland). Biochem. J. 100(1):19-26, 1966.

Samples of succus entericus were obtained from the jejunum of 4 sheep provided with jejunal loops, isolated by double reentrant fistulae, fitted with 4 cannulas for passing intestinal contents, for collection of samples, and also for the introduction of mild air pressure as a stimulant to secretion when desired. The loops were about 60-70 cm long and varied in position along the jejunum so that samples could be obtained from different levels of this section of the small intestine. The succus entericus when collected was centrifuged free of cellular debris. Protein content was determined by refractive index and also by the biuret method. Enzymes were produced in rabbits to the proteins of the jejunal fluid. Immuno-, paper and starch-gel electrophoreses were performed with the application of the appropriate staining reagents. Sedimentation-velocity studies were carried out in an ultracentrifuge at 279,700 times gravity. Thin layer chromatography was also employed in the separation of proteins. Hexose conc. in the intestinal secretion was determined. The loops secreted protein at a rate of 1-5 g/24 hr. The total protein in the fluid was about 2.5 times its serum albumin conc. The protein contributed by disruption of epithelial cells amounted to 60% of the protein in the fluid secretion. Comparison of the proteins in succus entericus with those in serum by immunophoretic and other electrophoretic methods showed 8 components in the fluid secretion to be the same as those in serum and 2 components which did not seem to be present in serum. Thin layer gel chromatography in Sephadex G-200 and sedimentation analysis showed that the intestinal secretion contained 2 proteins not present in the serum, 1 with a sedimentation coefficient (uncorrected) of 10s, and the other sedimenting more slowly than albumin; on gel chromatography the former moves with macroglobulin and the latter more slowly than albumin. These proteins could be secreted by the epithelial glands or released from desquamated epithelial cells. The hexose determined was not free sugar but the hexose in glycoproteins. The intestinal secretion consistently showed a higher conc. of glycoproteins than the serum.

8 THE IDENTIFICATION OF THE ANTIMICROBIAL FACTORS OF THE STOMACH CONTENTS

OF SUCKING RABBITS. (E.) Cañas-Rodríguez, A. (Chem. Res. Dept., Pfizer Ltd., Sandwich, Kent, England) and H. W. Smith. Biochem. J. 100(1):79-82, 1966.

Suckling rabbits have virtually sterile stomach and intestinal contents, prior to the development of acidic gastric secretion. Contents (clotted milk) removed from the stomachs of suckling rabbits were twice extracted with chloroform; the combined extracts were evaporated under reduced pressure yielding an oil called rabbit stomach oil (Oil I) which possessed antimicrobial properties; this oil contained 14% free fatty acids. Further steps, with constant testing for antibacterial action, produced successively purer oils; Oil III was hydrogenated and cooled; the liquid fraction was a mixture of fatty acids (Oil IV). Oil IV was separated into steam-

DIGESTION

volatile and nonvolatile acids. The steam-volatile fraction possessed 6-8 times the antibacterial activity of Oil I. The fatty acids in this fraction were identified as n-hexanoic, n-octanoic, n-decanoic, and lauric. Of these octanoic had 4 times and decanoic 8-10 times the antimicrobial action of Oil I. Commercially produced octanoic and decanoic acids have the same antibacterial activities. The paper presents in detail the methods of extraction, identification and analyses of the various components in the successive extractions from rabbit stomach oil.

- 9712 ON THE HETEROGENEITY AND PURIFICATION OF COMMERCIAL TRYPSIN PREPARATIONS (E.) Ganrot, P. O. (U. Lund, Sweden). Acta Chem. Scand. 20(1):175-182, 1966.

MOTILITY

- 713 PRESSURE EFFECTS OF TRANSABDOMINAL SUPRADIAPHRAGMATIC VAGOTOMY ON THE INFERIOR ESOPHAGEAL SPHINCTER OF DOGS. (E.) Elebute, E. (U. Rochester Sch. Med. Dent., New York), M. L. Kelley, Jr. and S. I. Schwartz. Surg. Gynec. Obstet. 123(2):326-332, 1966.

Gastroesophageal pressures were determined using both open and balloon tipped tubes connected to transducers in six dogs both before and up to 6 mo. after supradiaphragmatic bilateral vagotomy with antecolic gastrojejunostomy. The dogs were trained to lie supine on a table while measurements were being done in the unanesthetized state. The tube assembly was passed into the stomach and withdrawn 0.5 cm at a time, pressures being recorded at each step. The point at which pressure fluctuations changed from + to - with inspiration was considered the physiological status. Responses to deglutition were measured by water being inj. into the pharynx. Mean pressures at the end of inspiration and expiration were measured. The major effect of surgery was a significant decrease in gastroesophageal sphincteric pressure; no clear changes were seen with swallowing following vagotomy, nor was there evidence of effects on peristalsis in the body of the esophagus. The nearest effects were measured with the balloon unit which produced some degree of stretching of the smooth muscle fibers. It is suggested that the hypotonia of the crural portion of the gastroesophageal sphincter resulting from this operation may predispose to the reflux of gastric contents into the esophagus.

- 714 VARIATIONS IN THE FREQUENCY OF THE HUMAN DUODENAL BASIC ELECTRICAL RHYTHM IN HEALTH AND DISEASE. (E.) Christensen, J. (U. Iowa, Iowa City), J. A. Clifton and H. P. Schedl. Gastroenterology 51(2):200-206, 1966.

The slow regular variations in electrical potential of the duodenum (basic electrical rhythm, I) were recorded by a swallowable electrode. Duodenal activity was studied after a 6-16-hr. fast in 28 normal students and penitentiary inmates and 39 patients with a variety of diagnoses. The mean frequency in the 28 normals and 37 previous normals was 11.72 cycles/min.; no diurnal variation was noted. In 8 normals tested in a fever cabinet I frequency was correlated (0.74) with rectal temperature. Regression coefficient was 0.94 cycles/min./degree C. In 6 subjects given insulin (0.15 U/kg i.v.) 4 became hypoglycemic and their I frequency decreased. When propantheline, 3-60 mg i.v., was given to 11 subjects, no significant change was seen in I frequency. Two patients with thyrotoxicosis were studied during treatment; as the patients returned to normal their I frequency dropped to the normal range. A hypothyroid patient had a I frequency of 10/min. which normalized to 11.4/min. after treatment. In 3 hypoparathyroid and 2 hyperparathyroid patients all had low I frequencies. Eight patients with small bowel disease (1 true patient) all had low rates. Three patients with pulmonary insufficiency all had significantly low I frequencies. In 9 of 10 patients with functional bowel syndrome normal I frequencies were recorded. Of 11 other patients studied, only 1 with gastric ulcer had significantly lowered I frequencies. It is concluded that decreases in I frequency may be a nonspecific change due to illness; an increase however, is believed to be relatively specific, i.e. due to hyperthyroidism or fever.

- 715 GASTROINTESTINAL MOTILITY FUNCTION RELATED TO THYROID ACTIVITY. AN EXPERIMENTAL STUDY IN THE RAT. (E.) Johansson, H. (U. Uppsala, Sweden). Acta Chir. Scand. (Suppl. 359):1-88, 1966.

Thyroidectomized rats (treated with 2 µg thyroxine/day for 10 days) showed unchanged rate of gastric evacuation (GE) and intestinal propulsive mobility (IPM) showed no retardation as compared to untreated controls. With increased dosage (20 µg) or prolonged treatment (60 days), GE was accelerated and in animals admin. 20 µg for 60 days GE was twice as fast as in controls. IPM was accelerated in animals receiving 20 µg for 60 days. Dosages between the extremes (2 and 20 µg) and durations between 10 and 60 days did not increase IPM above that measured in controls. Speed of GE and IPM changed in thyro-parathyroidectomized animals with increasing length

MOTILITY

of postoperative period. At 38 days rates of GE and IPM were the same as for non-operated controls and at 60 days the rates were faster than in controls. O_2 consumption increased as thyroxine dosage increased, but there was no correlation between O_2 consumption and rates of GE and IPM within wide limits. Vagotomy caused a retardation of GE. Vagotomized rats when thyroidectomized showed further retardation of GE and also IPM. Admin. of thyroxine increased both functions indicating that they are not mediated through the vagus nerve. This method of measurement of GE and IPM, determinations of blood levels of thyroxine, and O_2 consumption are presented in great detail.

- 9716 BIOLOGICALLY ACTIVE POLYPEPTIDES. (Rus.) Radmanović, B. Z. (Med. U. Belgrade, Yugoslavia). *Srpski Arh. Celok. Lek.* 94(1):39-47, 1966.

In a review of the literature and report of personal studies it is shown that substance P (SP), a biologically active polypeptide, restored the peristaltic reflex in monkeys which was blocked by d-tubocurarine (d-T). This is probably due to an improvement in the reflex transmission through the parasympathetic ganglion. The studies on rabbits showed that the antagonism between SP and d-T depended on the doses used of d-T (linearly dependent on the dose logarithm), which indicates a specific antagonism between these two substances. Stimulation of the vagus caused an evacuation of the SP depots in the neural strictures of the intestinal wall, while a resection of the vagus enabled a filling up of these depots. After 3 days admin. of physostigmine the SP content in rabbit small intestine and brain was decreased. Therefore, SP, in addition to a direct myotropic effect, has an effect on the neural elements in the intestinal wall. A relationship exists between the central cholinergic mechanisms and SP.

- 9717 MOTOR RESPONSES OF HUMAN GASTROINTESTINAL TRACT TO 5-HYDROXYTRYPTAMINE IN VIVO AND IN VITRO. (E.) Misiewicz, J. J. (Cent. Middlesex Hosp., London), S. L. Waller and M. Eisner. *Gut* 7(3):208-216, 1966.

The effects of 5-hydroxytryptamine (5-HT; 0.5 mg/min. i.v., total dose 4 mg) on intraluminal pressures in the stomach, intestine and the proximal and distal colon were studied in 39 patients with a variety of gastrointestinal disorders by means of an ingestible telemetering capsule. Pressures in the sigmoid colon and rectum were recorded by air-filled balloons. In some patients colonic records were made following Prostigmin (0.75 mg i.m.). In vitro studies were done with strips of circular and longitudinal muscle obtained as surgical specimens. Muscle contractions were recorded against 1-3-g loads; the organ bath was filled with Krebs soln. 5-HT stimulated the small intestine both in vitro and in vivo. The response in vitro, 1-10 μ g/liter, was not antagonized by atropine, 1-10 μ g/liter; hexamethonium, 10-20 μ g/liter; procaine, 5-50 μ g/liter; pronethalol, 10-20 μ g/liter; or mepyramine, 5-20 μ g/liter. 5-HT inhibited colonic muscle both in vivo and in vitro. In patients, the onset was rapid and ended abruptly with the 5-HT infusion. The action in muscle strips was not inhibited by pronethalol, 5-10 μ g/liter; hexamethonium, 10-20 μ g/liter; mepyramine, 5 μ g/liter; or atropine, 10 μ g/liter. 5-HT was found to inhibit gastric motility, but had variable effects in vitro. All esophageal strips studied contracted in response to 5-HT, 0.5-10 μ g/liter. This effect was unreversed by any of the antagonists studied. The data collected were considered to suggest the site of action of 5-HT may be directly on smooth muscle. It was felt that 5-HT may be a factor in the production of the abdominal symptoms in the carcinoid syndrome.

- 9718 RESPONSE TO GASTROINTESTINAL PACING: ANTRAL, DUODENAL AND JEJUNAL MOTILITY IN CONTROL AND POSTOPERATIVE PATIENTS. (E.) Berger, T. (U. Göteborg, Sweden), J. Kewenter and N. G. Kock. *Ann. Surg.* 164(1):139-144, 1966.

The effect of pacing transluminal stimulation by means of a unipolar electrode and an electronic pacemaker on jejunal motility was studied postoperatively in 5 patients who had undergone partial gastrectomy, in 2 who had undergone repair of abdominal hiatal hernia and in 5 healthy subjects. Pressure waves reflecting motility were measured via a filled open ended jejunal tube connected to a pressure transducer. The electrode was placed distal to the gastroduodenostomy in the gastrectomized patients and in the antrum in the others. Recordings were collected

MOTILITY

ily as were responses to Prostigmin inj. The effect of pacing on gastric motility was measured in 5 patients without gastrointestinal disease by a similar procedure. Increase in the motor activity of the stomach, duodenum or jejunum was recorded during pacing either in normal subjects or in patients, although the sensitivity of the method was demonstrated by the inj. of Prostigmin. It was concluded that intestinal pacing will not contribute to the treatment of postoperative inhibition of the small intestine.

- 719 THE ACTION OF TERTIARY AND QUATERNARY ARECAIDINE AND DIHYDROARECAIDINE ESTERS ON THE GUINEA PIG ISOLATED ILEUM. (E.) Gloge, H. (Christian-Albrechts-U., Kiel, Germany), H. Lüllmann and E. Mutschler. Brit. J. Pharmacol. 27(1):185-195, 1966.

A series of tertiary and quaternary arecaidine esters as well as the corresponding hydro compounds were studied on the isolated ileum of the guinea pig. The effects of all compounds studied were compared with the dose-response obtained with arecoline. The dose response curves obtained were characterized by 1) intrinsic activity, max. effect, 2) affinity, reciprocal of the ED_{50} , 3) slope. The blockade of their agonistic action by atropine was also studied; compounds that had no intrinsic activity were evaluated for their influence on the effects of acetylcholine. The tertiary arecaidine esters were agonists; most potent were the ethyl ester and arecoline. Hydrogenation of the double bond in the ring reduces affinity and intrinsic activity of the tertiary esters. Hydrogenated esters act as inhibitors. Intrinsic activity is reduced or abolished by quaternization of the methyl and ethyl esters; esters with longer side-chains completely lose intrinsic activity and do not have atropine activity. Hydrogenation of the double bond in the ring of the quaternary compounds reduces their activity. In summary, in the arecaidine esters, quaternization of the ring nitrogen reduces or destroys intrinsic activity in proportion to the length of the ester side-chain.

- 720 CONTRACTION AND RELAXATION OF THE GUINEA-PIG'S TAENIA COLI IN RELATION TO SPIKE DISCHARGES. (E.) Mashima, H. (Juntendo U. Sch. Med., Tokyo), T. Yoshida and M. Handa. Jap. J. Physiol. 16(3):304-315, 1966.

A special chamber allowing the simultaneous recording of electrical activity and mechanical tension of the taenia coli of the guinea pig is described. Provision was also made for electrical stimulation and stretching of the preparation. It was found that with stretching the frequency of the spike discharge increased; spike frequency was a function of absolute tension after stretching. Frequency increased at max. stretching. The magnitude of spontaneous contraction decreased when synchronization of spike discharges occurred at max. tension. Following electrical stimulation the evoked contraction was followed by relaxation, which was not considered due to cessation of spike discharge or epinephrine release. It is concluded that the relaxation was due to the contraction itself lowering the inner visco-elasticity of the muscle cell.

- 721 ROENTGENOTONOMETRIC STUDIES OF THE MOTOR FUNCTION OF THE STOMACH. (Rus.) Meigal, Y. A. (Petrozavodsk U., USSR) and L. S. Mospanov. Ter. Arkh. 38(5):23-25, 1966.

Barium X-ray examination was combined with balloon gastrography in the investigation of 26 young men with gastric disorders: 9 with gastroduodenal ulcer, 12 with chronic gastritis, 4 with chronic cholecystitis, and 1 with cancer of the distal portion of the stomach. Gastromotor activity was normokinetic in 12, hypokinetic in 2, and hyperkinetic in 12. The results of the simultaneous studies showed 2 basic patterns: in one (17 of the 26 patients), the X-ray and gastrotonometric data coincided; in the other (8 patients), they did not. In 6 of the latter instances, the X-rays showed marked peristaltic activity of the distal portion of the stomach in the absence of waves in the "mechanogastrogram": the muscle wall of the fundus did not contract, and the pressure in the balloon did not change. In 3 other instances, peristaltic activity failed to appear in the X-ray when the gastrogram was registering active gastric motility. This second "dissociated" pattern shows how the 2 methods supplement each other. Since the X-ray method gives a clearer picture of the motor function of the distal portion of the stomach, whereas

MOTILITY

the gastrographic method best reflects that of the fundus and body of the stomach, their simultaneous application serves to reveal any dissociation in the motor function of different portions of the stomach. Also of practical interest was the finding (in 23 of the 26 cases) that merely placing the patient in front of the X-ray screen, before admin. of the contrast agent, inhibited gastromotor activity for 10-20 min. In 11 patients, another, briefer period of gastromotor inhibition, lasting for 5-10 min., followed the ingestion of barium acetate.

- 9722 THE EFFECT OF FREQUENCY OF COAXIAL ELECTRICAL STIMULATION ON THE PERISTALTIC ACTIVITY OF THE GUINEA-PIG ISOLATED ILEUM. (E.) Varagić, V. (Fac. Med., Belgrade, Yugoslavia) and T. Kažić. J. Pharm. Pharmacol. 18(8):513-518, 1966.

Isolated guinea pig ileum was maintained in a Tyrode soln. organ bath. Arrangements were made for stimulation by Paton's technic. Peristaltic activity was recorded by Varagic and Kazic's method. The ileum was perfused; the aboral end of the preparation was tied to a recording lever. Inflow pressure ranged from 15-30 mm water, outflow was measured by collection of the propelled fluid. The unstimulated gut showed regular peristaltic propulsive activity. Coaxial stimulation at high frequencies (100/min.) depressed activity; low frequencies (6/min.) either had no effect or stimulated peristalsis. Hexamethonium blocked all activity. Stimulation (5/second) had no effect on propulsive activity; 100/second reduced propulsion 85%. Duration of depression by high frequencies depended on the number of stimulations. Transfer to a new bath immediately after high frequency stimulation removed the inhibition completely. In the fatigued preparation (25-30 mm H₂O pressure "for a long time") stimulation produced peristaltic waves. Stimulation during the depression produced by high frequency stimulation by low frequencies reinstated peristalsis. Lowering bath temperature to 27° decreased propulsive activity; lowering to 20-23° blocked the effects of stimulation. It is concluded that the high frequency block is not due to something in the bath but might be due to activation of inhibitory elements in the gut.

- 9723 MECHANICAL ACTIVITY OF THE DUODENUM, OF THE TERMINAL TRACT OF THE COMMON BILE DUCT, AND THE DUCT OF WIRSUNG. (It.) Cassano, C. (U. Rome, Italy), A. Torsoli and M. L. Ramorino. Minerva Med. 57(31):1383-1394, 1966.

The authors correlate a review of the literature with observations on 310 human subjects (normal or with gastrointestinal symptoms) and express the opinion that physiological findings do not support the view that duodenal disease is an important factor in causing pancreatic or gallbladder disease by reflux through the ducts. Technics used include transhepatic cholangiography, X-ray cinematography, and transcholedochal radiomanometric methods. Duodenal non-propulsive activity is of tonic and local phasic types; the former maintains a basic pressure lower than that of the common duct. Mechanical stimuli are chiefly responsible for "long transport" propulsive activity, whereas pancreatic-biliary secretions evoke "short transport" waves and local phasic activity which cause mixing and dilution. The ampulla and terminal parts of the ducts possess a tonic closure activity which is interrupted by rapid phasic movements of opening and closure. The former proceeds in a superior to inferior direction. Closure begins at the level of the papilla and obliterates the ducts from below upward; at the same time, a contraction proceeds in the opposite direction. Overdistention of the duodenum opposes rather than favors reflux into the ducts. Variations in intraluminal pressure are transmitted to the ducts when the sphincter is relaxed, but not while it contracts. Distention of the cystic-hepatic-common duct junction is followed immediately by phasic motility of the second part of the duodenum, presumably by nerve reflex. Spread of mucosal inflammatory changes to the papilla or hypertonic dyskinesia of the second part of the duodenum can cause obstruction of ductal emptying and stasis. Duodenal-ductal reflex is rare and usually caused by anomalous insertion of the ducts or an inadequate sphincter. Automatic closure of the ducts remains efficient after papillotomy or sphincterotomy.

- 9724 A TELEMETERING SYSTEM FOR SECURING DATA ON THE MOTILITY OF INTERNAL ORGANS. (E.) Lonsdale, E. M. (U. Wyoming, Laramie), J. W. Steadman and W. L. Pancoe. IEEE Trans. Biomed. Engin. 13(3):153-159, 1966.

elemetering system approx. 15 by 20 mm using an elongation sensor is described, data collected after implantation in a rat presented. A novel feature of the system is a circuit allowing the unit to be turned on or off when brought into the vicinity of a pulsed radio frequency signal. The implantable transmitter is basically a Hartley oscillator using the capacitive reactance of the sensor to produce frequency modulation. The usable range was in excess of 20 m. The pulsing oscillator used to start or stop the transmitter was a self-excited oscillator used for grid-blocking action. The self-blocking was due to a long time constant in the biasing circuit. The transducer developed was a variable capacitor formed by winding 2 insulated wires in a helix. The sensor was coated with latex rubber covered with silicone grease. The receiver used was a commercial FM operations receiver; an oscilloscope was connected across the discriminator output. The sensor was attached to the fundus of a rat, the transmitter to the abdominal wall. Respiratory changes, feeding patterns, normal motility and effects of fright and atropine were all recorded. Transducer action deteriorated after several months due to seepage of body fluids; problems were also encountered in stabilizing zero-set drifts.

5 THE HUMAN SMALL INTESTINAL SLOW WAVE. (E.) Clifton, J. A. (U. Iowa, Iowa City), J. Christensen and H. P. Schedl. Trans. Am. Clin. Climat. Assn. 77:217-225, 1966.

An electrode allowing recording of the changes in electric potential of the intact intestine (basic electrical rhythm, BER) consists of a hollow capsule attached to a flexible cable with a copper core, electrically connected to a silver wire protruding into the chamber of the capsule, which is filled with 3 M KCl. A cotton plug acts as a plug for a hole in the capsule and as contact with the mucosa. The capsule is attached to a water-filled balloon allowing concurrent pressure recording. The other electrode for BER recording is placed on the abdomen. Respiration recorded by a thermistor in the air stream. In 65 normal subjects, 18-45 yr. of age, the av. BER was 11.72 (SD = 0.38). No variations in frequency were found throughout the duodenum, nor were diurnal variations noted. A descending gradient in BER frequency was determined in 12 normal subjects; breaks in the gradients occurred when the electrode was 90-120 and 190-200 cm from the incisor teeth. Rectal body temperature in 8 normal subjects correlated ($r = 0.74$) with BER; the regression coefficient was 0.93 cycles/min./°C. Hypothyroidism and hyperthyroidism (11 and 22 patients, resp.) significantly affected the BER; av. BERs were 9.94 and 13.81. Low rates were seen in patients with gastric ulcer, pulmonary insufficiency, Whipple's disease and parathyroid disease. No drugs studied, including anticholinergics and adrenergic blockers, were able to change the BER. Hypoglycemia, however, reduced the BER; in 1 patient probanthine reversed this effect.

6 AN ANALYSIS OF THE ACTION OF DRUGS ON THE CIRCULAR MUSCLE STRIPS FROM THE CAECUM OF THE GUINEA-PIG. (E.) Akubue, P. I. (U. Ibadan, Nigeria). J. Pharm. Pharmacol. 18(8):490-500, 1966.

Guinea pig taenia-free circular muscle strips were cut and suspended in an organ bath of Krebs soln. Responses were recorded with a load on the muscle of approx. 100 mg. The strips when suspended went slowly into max. contracture in 1-2 hr. A "tone" lasted over 8 hr. and was not abolished by hyoscine (0.1 to 1.0 µg/ml). The latent time of drugs was 45 seconds, interval between doses was 4 min. The tissue was incubated 30 min. before testing with an antagonist drug. Acetylcholine contraction threshold was approx. 0.1 µg/ml. This response was potentiated by the anticholinesterase, mipafox, and abolished by hyoscine (0.1 µg/ml). Histamine (1 µg/ml) produced contractions unaffected by mipafox or hyoscine. 5-Hydroxytryptamine (5-HT; 0.1 µg/ml) produced contractions which reversed to inhibition at high doses; mipafox enhanced the effects, while hyoscine and local anesthetics inhibited them. Nicotine produced relaxation but produced contractions after mipafox. The site of action of acetylcholine and histamine was thought to be on smooth muscle cells since pentolinium, dimethylphenylpiperazinium, procaine and cocaine failed to block their actions. Nicotine was thought to activate adrenergic ganglion cells; contractions induced by nicotine were blocked by hyoscine, local anesthetics and ganglionic blocking agents. The responses to 5-HT

MOTILITY

were not affected by pentolinium but were reduced by dimethylphenylpiperazinium. It was concluded that the action of 5-HT was due to activation of specific receptors on the cholinergic nerves. One part of this action was assumed to be located on the ganglion cells.

- 9727 THE EFFECT OF ANALGESIC DRUGS ON THE RELEASE OF ACETYLCHOLINE FROM ELECTRICALLY STIMULATED GUINEA-PIG ILEUM. (E.) Cox, B. M. (St. Mary's Hosp. Med. Sch., London) and M. Weinstock. Brit. J. Pharmacol. 27(1): 81-92, 1966.

Lengths of guinea pig mid-ileum (7 cm) were tested in an organ bath containing Krebs soln. in a manner similar to that of Paton (1955). Tissue was stimulated by single shocks every 20 seconds adjusted to give max. response. Drugs were left in contact with tissue not longer than 2-3 min. Doses inhibiting electrically stimulated contractions more than 85% were avoided. Contractions were allowed to return to their initial height between each dose. Conc. of acetylcholine in the bath was determined for each drug level after the addition of physostigmine (5 µg/ml raised to 50 µg/ml) for assay on the dorsal muscle of the leech. Morphine reduced contractions of the ileum to transmural stimulation at conc. as low as 4.7 µg/ml. A close correlation was found between % reduction in contraction height by morphine and acetylcholine release. Three groups of compounds were tested: 1) morphine derivatives, 2) morphinan derivatives and 3) oripavine derivatives. Replacement of the 3-hydroxyl group by a methoxy group reduced potency in all 3 groups; an acetyl group in the 3 position increased inhibitory potency. Inhibition of contraction height was found to be correlated with analgesic potency. Isomeric pairs of compounds were tested and in each case the levo-isomer depressed contractions similarly to morphine. The dextro-isomers were inactive at doses up to 100 times greater. As with morphine, acetylcholine release was correlated with activity on the ileum. The effects of morphine were not antagonized by concurrent admin. of nalorphine or levallorphan; however, if they were applied 12 min. before morphine they were effective. This antagonism was specific inasmuch as epinephrine inhibition was not antagonized. Low doses of nalorphine and levallorphan were without inhibitory activity.

- 9728 FORCE AND FREQUENCY OF CONTRACTION OF DIFFERENT INTESTINAL SECTIONS OF THE DOG IN VIVO. (Ger.) Rinecker H. (U. Surg. Clinic, Munich, Germany) and W. Brendel. Pflueger. Arch. Ges. Physiol. 290(2):144-157, 1966.

An in vivo method using up to 4 permanently-implanted isometric devices and strain gauges measured rhythm and intensity of peristalsis in unanesthetized dogs. Disturbances in the recording due to respiratory movements were eliminated. The highly periodic contractions (contraction waves produced sinusoid curves) seemed to cover long distances in the intestine; only the colon showed additional aperiodic movements. The various intestinal sections had constant and characteristic contraction frequencies which could be altered by prolonged anesthesia, but not by atropine (0.030 mg/kg i.v.), neostigmine (0.07 mg/kg i.v.), or cholecystokinin (2.5-5.0 Ivy dog U/kg). The intensity of the peristaltic waves showed considerable fluctuation, mostly spontaneous. In the jejunum the values were always above zero a complete resting stage could be seen occasionally only in the pyloric antrum. The above doses of neostigmine and atropine caused an increase or a decrease in strength of contraction. Cholecystokinin produced within 30 seconds a sudden increase in the strength of contraction, all along the pyloric antrum, duodenum, jejunum, and ileum. The relative constancy of peristaltic frequency even under the influence of synaptic and sympathomimetic drugs, but easy variability of strength of contraction under the influence of synaptic drugs suggest that autonomic control of transport through the digestive tract is chronotropic rather than inotropic. Since the periodic contraction waves cause only minor constriction of the intestinal lumen, this transport must proceed at a slower rate than one would infer from the velocity of the contraction waves.

- 9729 INHIBITION OF GASTRIC CONTRACTION FOLLOWING STIMULATION OF INTRATHORACIC SENSORY ENDINGS. (E.) Bevan, J. A. (U. California Med. Ctr., Los Angeles) and T. Hughes. Arch. Int. Pharmacodyn. 161(2):334-342, 1966.

tronic motor activity was recorded by a water-filled balloon in 18 cats anesthetized with α -chloralose. Femoral arterial pressure, electrocardiogram and respiratory movement were also recorded. Drug inj. were made via cannulae into the right atrium and left ventricle. In 4 cats a bilateral subdiaphragmatic vagotomy was performed; in 3 the spinal cord was sectioned (4th or 5th cervical) 2-6 days before experiment. Fifteen $\mu\text{g/kg}$ of lobeline and 12 $\mu\text{g/kg}$ of phenyldiguanide inj. into atrium or ventricle invariably inhibited the spontaneous contractions of the stomach. Tone was decreased in the absence of contractions. The inhibition occurred 1.27 seconds after reflex bradycardia. The threshold for cardiovascular and gastric effects was the same; the inhibition of one was never seen in the absence of inhibition of the other. Gastric inhibition following ventricular inj. of either drug disappeared when the same doses were inj. into the ascending aorta distal to coronary ostia. Large doses inj. into the descending thoracic aorta had no effect on gastric activity. Vagotomy abolished lobeline and phenyldiguanide inhibition on the gastric system but not on the cardiorespiratory triad. Epinephrine (4 $\mu\text{g/kg}$; i.v.) abolished gastric movements. Spinal section had no effect on drug inhibition. It is concluded that the inhibition was mediated by the parasympathetic nervous system since it was abolished by vagotomy and not by spinal section.

GASTRIC EMPTYING IN RATS AFTER PART-BODY IRRADIATION. (E.) Hulse, E. V.
(Radiobiol. Res. Unit, Harwell, Didcot, Berkshire, England). Int. J.

Radiat. Biol. 10(6):521-532, 1966.

Rats (3-6 mo. old) carefully trained to eat a barium meal and conditioned to a plastic restraint tube, were fasted overnight, fed the radio-opaque meal and radiated. Preliminary radiographs were taken. After radiation serial radiographs were taken every half hr. for 3 hr. and then every hr. until 8 hr. had elapsed. Both lateral and postero-anterior views were taken. Twenty to 200 r were delivered to various parts of the body. The vol. of the stomach was assessed from the radiographs at various times after radiation and expressed as a % of the preradiation value. All estimates were performed blind. Irradiation (100 r) of the caudal half of the body delayed emptying equally with whole body irradiation of 100 r. Animals irradiated in 100 and 200 r to the head and shoulders and 20 r whole body were similar to controls in stomach emptying. Whole body 50 r delayed emptying but less than with 100 r. When segments of the caudal half of the body were irradiated it was found that 100 r to the caudal 1.5 in. had no effect, irradiation of the 3 in. cephalic half (100 r) equaled whole body 100 r. These segments contained the stomach and the small intestines. Radiation (100 r) of the left side was slightly less effective than either whole body or right side irradiation. Irradiation of the dorsal half had greater effect than irradiation of the ventral half of the body. Irradiation of the ventral half of the abdomen was more effective than of the dorsal half. Irradiation through a 1-in. port had less effect than whole body irradiation; a 1-in. protective block decreased emptying similarly to whole body irradiation. On the basis of these findings it is tentatively concluded that the most likely organs contributing to the delay were the small intestines and its associated structures such as the ganglia and plexi of the autonomic nervous system.

THE EFFECT OF 6-AZAURODINE ON THE CONTRACTILE RESPONSES OF THE ISOLATED ILEUM OF THE GUINEA-PIG TO DRUGS AND TO COAXIAL STIMULATION. (E.)

Šeferná, I. (Charles U., Prague, Czechoslovakia), N. Loukomska, O.

Kadlec and I. Janků. J. Pharm. Pharmacol. 18(8):501-506, 1966.

Low doses of 6-azauridine (6-AU; 200-400 $\mu\text{g/ml}$) increased the responses of terminal ileum of guinea pig to nicotine, acetylcholine, histamine and barium chloride; in each case the dose producing approx. 40% max. response was tested. Contact with 2 mM 6-AU up to 48 min. reduced the contractions produced by the spasmogenic agents. This inhibition was reversible by soln. change. Low conc. of the drug potentiated the response to coaxial stimulation, high conc. (20 mM) produced sustained inhibition, which was not reversible. No significant differences were found in acetylcholine release, spontaneously or following coaxial stimulation before or after prolonged exposure to 20 mM of 6-AU. It is noted that, like papaverine, 6-AU did not affect the acetylcholine output of the ileum, although its effects differed in that they were not readily reversible. It is concluded that the drug acts directly on the smooth muscle cells.

MULTIAXONAL AUTONOMIC JUNCTIONS IN INTESTINAL SMOOTH MUSCLE OF THE TOAD (*Bufo Marinus*). (E.) Rogers, D. C. (U. Melbourne, Parkville, Victoria Australia) and G. Burnstock. *J. Comp. Neurol.* 126(4):625-633, 1966.

Light and electron microscopic studies of innervation of the small and large intestine circular smooth muscle coats of the toad, *Bufo marinus*, demonstrated a pronounced difference in the nerve plexus organization in the muscle coats of the 2 regions. In the small intestine (1 inch below the pylorus), 'multiaxonal junctions' are common wherein groups of axons with Schwann cell sheath come into close apposition (150 Å) with the tips of smooth muscle cells. An axon may be in close relationship to more than one smooth muscle cell at one particular locus. In the large intestine (colon-rectum region) single axons diverge from large nerve bundles and come to lie, free of the Schwann sheath, in shallow grooves in the muscle cells. Each muscle cell can have several widely separated single axon junctions of this type. The axons both in Auerbach's plexus and in the terminal part of the ground plexus contain clumps of agranular vesicles, small, dense glycogen-like granules and large, membrane-limited granules. The axons are less than 100 Å apart.

9733

THE ACTION OF NORADRENALIN (NOREPINEPHRINE) AND ADRENALIN (EPINEPHRINE) ON THE MOTOR FUNCTION OF THE GALLBLADDER. (Rus.) Byvshuk, N. S. (Tern Med. Inst., USSR). *Farmakol. Toksik.* 29(3):334-337, 1966.

L-Epinephrine hydrochloride and L-norepinephrine bitartrate, admin. i.v., depressed the motor function of gallbladder of 5 dogs with permanent gallbladder fistula by Schiff; the depression caused by L-epinephrine was 1.5 times greater than that caused by L-norepinephrine. L-Epinephrine and L-norepinephrine, when tested in small (1-5 µg/kg), medium (5-15 µg/kg) and larger (20-30 µg/kg) doses, showed that the degree of inhibition (intensity and duration of action) increases with increase in dose. The adrenolytics, ergotal (50 µg/kg, i.v.) and dibenamine (3 mg/kg, i.v.), did not eliminate the action of L-epinephrine and L-norepinephrine on the gallbladder motoricity. Preliminary i.v. admin. of chlorpromazine (15 mg/kg, i.v.) decreased the action of L-norepinephrine on gallbladder motoricity. The depression action of L-norepinephrine and L-epinephrine on the gallbladder usually lasted 10-30 min. after admin. and could be easily reversed by cholinomimetics, carbacholine and proserine. L-Epinephrine and L-norepinephrine could depress motility and decrease the tonus of the gallbladder even when pressure had been elevated by cholinomimetics.

HEPATIC METABOLISM

STUDIES ON THE INDUCTION AND REPRESSION OF ENZYMES IN RAT LIVER. IV. EFFECTS OF CORTISONE AND PHENOBARBITAL. (E.) Peraino, C. (U. Wisconsin Sch. Med., Madison), C. Lamar, Jr. and H. C. Pitot. J. Biol. Chem. 241(12):2944-2948, 1966.

Effects of cortisone on the dietary induction and repression of serine dehydratase, ornithine transaminase, and tyrosine transaminase are presented. In rats treated with cortisone, dietary induction was little affected, but glucose repression was eliminated. Cortisone alone produced no induction. The effects of cortisone and phenobarbital on the dietary induction of serine dehydratase and ornithine transaminase are also presented. Pretreatment with phenobarbital had little effect on the induction of the above two enzymes, but pretreatment with cortisone and phenobarbital together caused an increased response to casein hydrolysate feed. Neither cortisone nor phenobarbital, admin. alone or in combination, produced induction in the absence of casein hydrolysate, the dietary inducer. Additionally, it was shown that insulin is not the primary agent in the phenomenon of glucose repression of serine dehydratase.

THE EFFECT OF ADRENALECTOMY AND STARVATION ON ARGINASE AND ORNITHINE-TRANSCARBAMYLASE ACTIVITIES IN THE LIVER OF RATS DURING DEVELOPMENT. (E.) Illnerová, H. (Inst. Physiol., Czech. Acad. Sci., Prague). Physiol. Bohemoslov. 15(1):23-26, 1966.

Arginase (I) and ornithine-transcarbamylase (II) activity in 19-day-old adrenalectomized rats was lower than in sham-operated controls, being essentially the level of that of 14-day-old rats. Two days of water and food deprivation increased both I and II activity in 11-day-old rats; this effect was decreased if they were admin. I activity did not increase in starved adrenalectomized 11-day-old rats while normal increase was seen in sham-operated animals. II activity was raised by starvation after adrenalectomy or in the sham-operated rats. It is concluded that corticosteroids play an important role in the regulation of I and II activity postnatally, and are necessary for the increased activity after day 14.

TEMPORARY USE OF EX-VIVO HETEROLOGOUS LIVER FOR HEPATIC INSUFFICIENCY: METABOLIC EFFECTS AND SENSITIVITY TO PERFUSED PROTEIN IN DOGS. (E.) Bibler, D. D. (U. Washington Sch. Med., Seattle), R. E. Condon and L. M. Nyhus. Ann. Surg. 164(1):61-68, 1966.

4 dogs with advanced hepatic failure (produced by an Eck fistula and 70% hepatectomy) were subjected to hemoperfusion through a bovine liver for 2 hr., the metabolism of sulfobromophthalein (5 mg/kg) and galactose (500 mg/kg) was improved during the temporary use of the ex-vivo heterologous liver. However, 2 dogs still in state of hepatic insufficiency suffered anaphylactic reactions within 5-7 min. after i.v. inj. with bovine plasma 11-35 days after the perfusion. In addition, anisocytosis, hemolysis and elevated levels of serum glutamic-oxalacetic transaminase were associated with each perfusion. Despite these hazards, the use of an ex-vivo heterologous liver obviates the risks of transmission of disease and immediate immunologic reaction to the donor involved in cross circulation.

HEPATIC INTRACELLULAR DISTRIBUTION OF TRITIUM-LABELED UNCONJUGATED AND CONJUGATED BILIRUBIN IN NORMAL AND GUNN RATS. (E.) Bernstein, L. H. (Albert Einstein Coll. Med., New York, N. Y.), J. Ben Ezzer, L. Gartner and I. M. Arias. J. Clin. Invest. 45(7):1194-1201, 1966.

Intraj. of tritium-labeled unconjugated bilirubin (UCB-H³) in glucuronyl transferase-deficient (Gunn) rats or its addition in vitro, the distribution of radioactivity was significantly reduced in the microsomal fraction and correspondingly increased in the supernatant fraction. In contrast, after inj. of tritium-labeled conjugated bilirubin (CB-H³) or its addition in vitro, the subcellular distribution was the same as that seen in normal rats after inj. or in vitro addition of either UCB-H³, CB-H³ or UCB-C¹⁴ which showed approx. 60% of intrahepatic radioactivity in the supernatant fraction and 25% in the microsomal fraction. It appears that unconjugated bilirubin is transferred from plasma into the cytoplasm of the liver

HEPATIC METABOLISM

cell and glucuronyl transferase may be a binding site for this transfer. After infusion of UCB- H^3 to normal rats, CB- H^3 could not be recovered from cell fractions and the absolute radioactivity in lysosomes remained constant, which indicates that conjugated bilirubin is not stored in the liver but is rapidly excreted by a process which does not involve lysosomes.

- 9741 A HETEROGRAFT MODEL FOR AUXILIARY LIVER TRANSPLANTATION IN THE DOG. (E.) Pangan, J., Jr. (New York State U. Downstate Med. Ctr., Brooklyn), L. Popowitz, L. Sobocinski, S. Minkowitz, A. S. Josephson, C. Valenti and M. L. Gliedman. Trans. Am. Soc. Artif. Intern. Organs 12:265-274, 1966.

Heterografts of liver from a number of species into the dog as host were suggested after examination of karyotypes revealed that those of the dingo, dog, and coyote are indistinguishable in size, number ($2n = 78$), and architecture. The diploid number is 38 in the fox which is also true in the pig although the architecture is quite different. Immunologic studies showed no cross-reactivities for any of the species and the dog, except for the pig where cross-reactivity was minimal. Implantation of coyote and dingo livers into the dog proved impractical because of the large size of the donor organs. A number of immunorepressive regimens were used. Seventeen fox-to-dog transplants were made. The longest graft function was 14 days, equal in duration to a homograft. Nine transplants accomplished without technical difficulties and judged to be satisfactory at the time of closure of the abdominal cavity had decline and cessation of bile production in 24-36 hr. The porcine graft became congested and function ceased in a short time. Ex-vivo perfusion of dog, fox and pig livers were tried; these lost function in a few hr.

- 9742 THE DISTRIBUTION OF BILIRUBIN IN RAT LIVER FRACTIONS. (E.) Hargreaves T. (St. George's Hosp. Med. Sch., London, S. W. 1) and G. Scrimgeour. Experientia 22(6):382-383, 1966.

The distribution of bilirubin in various subcellular compartments of liver tissue was determined in 14 male and female jaundiced Gunn rats and also in Wistar rats infused with bilirubin soln. until the serum level of bilirubin reached that of Gunn rats (8-12 mg%). The general distribution was the same in the two series. The distribution in descending order was cell sap, nucleus, mitochondria, and microsomes. The microsomal fraction of Gunn rats contained less bilirubin than that of Wistar rats. (The microsomes are the locus of uridine diphosphate transglucuronylase, deficient in Gunn rats.) The liver cell sap of Gunn rats contained more bilirubin than the cell sap of Wistar rats. The possibility exists that the bile pigment is bound to proteins of serum and cell sap. In addition, the distribution of bilirubin in the tissues of various organs was investigated in 7 male and 7 female Gunn rats. Almost identical mean values were found for the same organs of male and female, liver having the highest conc. (62 μ g/g) and brain the lowest conc. (12 μ g/g).

- 9743 STARVATION-INDUCED ADAPTATION OF RAT LIVER TYROSINE TRANSAMINASE AND SERINE DEHYDRASE. (E.) Goswami, M. N. D. (U. Paris) and F. Chatagner. Experientia 22(6):370-371, 1966.

Male Wistar rats, 4 wk old, were placed in 2 main groups: (1) adrenals intact and (2) adrenalectomized; in main group (1) were 3 subgroups: fed, starved 48 hr. and starved 48 hr. plus i.p. glucose; in main group (2) were 4 subgroups: fed, starved 48 hr., starved 48 hr. plus i.p. glucose, and starved 48 hr. plus puromycin. The livers were prepared as 33% homogenates in 0.25 M sucrose in the cold and centrifuged under refrigeration at 105,000 g for 45 min. Enzyme activities were determined in the supernatant under conditions in which the reaction rates were linear with time and enzyme conc. The supernatants from each subgroup were tested for tyrosine transaminase activity in terms of μ moles p-hydroxyphenyl-pyruvate produced per hr. and for serine dehydrase activity in terms of μ m pyruvate produced per hr. Starvation for 48 hr. induced an increase in liver transaminase and serine dehydrase in adrenalectomized rats, as well as in intact animals. The degree of increase was even higher after adrenalectomy due to lowering of basal enzyme level. This liver serine dehydrase was depressed as much as 50% by adrenalectomy; the effect of starvation was to increase the enzyme level 6-7 fold.

ATIC METABOLISM

pared to a 2-3-fold increase in the intact, starved rats. The enzyme increases reduced about 40% by puromycin. Enzyme elevation was reduced or suppressed by those; no specific enzyme inhibitors could be detected. The enzyme elevation during starvation was not accompanied by an increased substrate conc. The enzyme decrease during starvation (with or without corticoids) may be caused by energy requirements for homeostasis ultimately contributed by protein catabolism.

A STUDY OF INTERNAL DISTRIBUTION OF IRON IN MAN. (E.) Hosain, F. (U. Washington Sch. Med., Seattle) and C. A. Finch. Acta Med. Scand. 179(Suppl. 445):256-263, 1966.

groups of subjects (normal, iron deficiency, idiopathic hemochromatosis, ineffective erythropoiesis, and aplastic anemia) were admin. i.v. transferrin-bound (5-40 μ c Fe⁵⁹) incubated with normal plasma or p.o. radioiron (20-100 μ c Fe⁵⁹). *in vivo* counts, liver and splenic areas, were done periodically for 14 days, and compared to *in vitro* (blood sample) counts. In patients with increased parenchymal iron the liver-splenic ratio was increased in proportion to tissue deposition. Serum iron or saturation of transferrin was usually associated with deposition of iron in the liver parenchyma. Less liver iron deposition occurred as part of breakdown within the reticuloendothelial system. Usually oral and i.v. admin. were similarly distributed; in patients with iron overload and saturated transferrin there was evidence of direct hepatic uptake of iron. It is concluded that surface monitoring indicated the general distribution of absorbed iron indicated if this iron was distributed by the normal plasma transport mechanism.

HISTOLOGIC STUDY OF THE LIVER AND SPLEEN AFTER INTRAVENOUS INJECTION OF LIPIODOL EMULSION IN THE MOUSE. (Fr.) Dalion, J. (U. Paris Sch. Med., Sorbonne), M. Guerbet and A. Delaville. C. R. Assn. Anat. (131):354-363, 1966.

Following i.v. inj. of 3 g/kg iodinated poppyseed oil into white mice, 9% of the iodine was recoverable from the spleen after 24 hr., 26% from the liver. In some cases, the soluble iodine fraction was degraded and eliminated through the excretory system within a short time, while some of the lipid fraction was still detectable 48 hr. later.

EFFECT OF DIETS MARGINAL IN METHIONINE AND CHOLINE WITH AND WITHOUT VITAMIN B₁₂ ON RAT LIVER AND KIDNEY. (E.) Newberne, P. M. (Massachusetts Inst. Tech., Cambridge) and V. R. Young. J. Nutr. 89(1):69-79, 1966.

Long rats, individually caged, maintained at 21-27°, were freely supplied with food and water. The food for different groups of rats varied in methionine and choline content and in the presence or absence of vitamin B₁₂ as an additive. Weights were recorded weekly. Blood was withdrawn under anesthesia just before necropsy. Necropsy was performed on all animals. Tissues were preserved for microscopic study. The low-methionine, low-choline groups gained wt. more slowly than other groups. At 6 mo., however, their wt. was as good or better than the controls. The groups low in methionine and low in choline with added vitamin B₁₂ had the highest wt. at 6 mo. High-methionine and high-choline groups had no explained wt. loss between 3 and 6 mo. A high proportion (87-90%) of the animals fed the low methionine and low choline diets showed striking microscopic lesions in the inner cortex of the kidney and also noncalcified, mucoid structures in the urinary bladder. Addition of methionine, choline and vitamin B₁₂ to the diet prevented all abnormalities. The liver was histologically normal and unaffected by low methionine and low choline intake. Total plasma proteins and albumin fractions were not affected except for a decrease of gamma globulin in the low-methionine, low-choline groups.

HEPATIC AND MESENTERIC ARTERY RESISTANCES AFTER SINOARTIC DENERVATION AND HEMORRHAGE. (E.) Mundschauf, G. A. (U. Wisconsin Med. Sch., Madison), S. W. Zimmerman, J. W. Gildersleeve and Q. R. Murphy. Am. J. Physiol. 211(1):77-82, 1966.

Following hemorrhage, mesenteric resistance increased and was 100% above the control level 15

HEPATIC METABOLISM

min. after sinoaortic denervation, regardless of whether the blood pressure was or was not stabilized after the denervation. After the denervation, gastroduodenal resistance increased 50% above control. Hepatic artery flow (with all branches intact) increased as the blood pressure increased; but with the gastroduodenal artery ligated, the hepatic artery flow increased 50% during the first min. after denervation and returned to near control level within 5 min. Following hemorrhage (3% of body wt.), mesenteric resistance increased 130% and hepatic arterial resistance 10%, with gastroduodenal artery ligation. The dogs were anesthetized with morphine and chloralose. These data indicate that both mesenteric and hepatic beds can be influenced by central neurogenic control, but the influence is greater and longer on the mesenteric flow.

- 9748 STUDIES OF THE FUNCTIONAL RELATIONSHIP BETWEEN HEPATIC PARENCHYMA AND MESENCHYME. EFFECTS OF AN ANTIGEN ON THE CLEARANCE OF INDOCYANINE GREEN (Ger.) Lang, N. (U. Marburg/Lahn, Germany), H. Bonisch and S. Bruck. Gastroenterologia (Basel) 105(5):294-300, 1966.

In adult rabbits, Indocyanine Green (1 mg/kg, i.v.), inj. 5-15 min. after pretreatment with glutamic-oxalacetic transaminase or human albumin (0.4 mg, i.v.), cleared from the blood stream at a significantly faster rate than was seen in controls or in rabbits inj. with the dye 1-2 days before treatment as above. Two days later, the clearance rate was approx. normal; then a second, and even more marked, acceleration was seen, beginning about day 5 and lasting 4-5 wk. Increase of the protein dosage to 0.8 or 1.6 mg destroyed the initial effect, although the delayed effect was still evidenced; while i.p. inj. destroyed both effects. In animals with severe liver damage, induced by pretreatment with CCl₄, substantially identical responses were seen, although normalization of the clearance rate followed more quickly. In all responding animals, the max. increase of antibodies in the peripheral circulation following inj. of glutamic-oxalacetic transaminase occurred 2-7 days after the max. acceleration of dye clearance. Since the dye was absorbed and excreted by the liver parenchyma and the protein induced increased activity of hepatic mesenchymal reticuloendothelial cells, it is concluded that the latter activation increased at least certain aspects of parenchymal function directly until equilibrium had been re-established.

- 9749 ANIMAL EXPERIMENTAL STUDIES OF THE LYMPHAGOGIC, DIURETIC AND CHOLERETIC EFFECTS OF VARIOUS ALCOHOLS. (Ger.) Vogel, G. (Madaus Inst. Biol., Cologne, Germany), G. Lehmann, E. Meyering and B. Wendt. Arzneimittelforschung 16(5):673-677, 1966.

When admin. to rats intraduodenally, neither export beer, bock beer nor a water-ethyl alcohol mixture of equivalent alcoholic content showed any choleretic effect. However, it is suggested that a cholecystokinetic effect may be possible in man, due to contractile evacuations of the gallbladder following admin. per os.

- 9750 BILE ACID AND CHOLESTEROL METABOLISM IN THE MOUSE AS AFFECTED BY CHOLESTYRAMINE. (E.) Beher, W. T. (Henry Ford Hosp., Detroit, Mich.), M. E. Beher and B. Rao. Proc. Soc. Exp. Biol. Med. 122(3):881-884, 1966.

The rate of mobilization of blood and liver cholesterol in mice (female, Webster strain) was increased by diets supplemented with 1% cholestyramine. The bile acid turnover rate was 4 times as fast in mice treated with cholestyramine while the bile acid pool size was smaller than that of the controls. This pool was shown to consist almost exclusively of cholic acid, regardless of the type of diet. The daily rate of synthesis of bile acids in normal mice was 0.56 mg, whereas the rate was 1.84 mg in cholestyramine-treated mice; digitonin-precipitable fecal sterol excretion measured 5.5 and 7.58 mg/day, resp. To effect accumulation of blood and liver cholesterol, all diets were supplemented with 1% cholesterol and 0.5% cholic acid.

- 9751 REGENERATION OF THE MAMMALIAN LIVER. IV. EVIDENCE ON THE ROLE OF CYTOPLASMIC ALTERATIONS IN PREPARATION FOR MITOSIS. (E.) Becker, F. F. (New York U. Sch. Med., New York) and B. P. Lane. Am. J. Path. 49(2):227-238, 1966.

rats (about 250 g) were used in a series of experiments performed to determine the significance of changes in the lysosome system during the first 12 hr. following hepatectomy (the period of the induction of the synthesis of nucleic acid). Animals were sacrificed at 0-12 hr. At each of these times tissues from 3 animals were obtained for electron microscopy. In addition to the 70% hepatectomy *per se*, the following operations and procedures were performed using rats, the liver tissues of which were preserved for electron microscopy: (1) Starvation (24 hr.), followed by 70% hepatectomy; (2) inj. of 250 μ g/kg body wt. of actinomycin D at the time of hepatectomy; (3) 45% hepatectomy; (4) inj. of chloroquine and quinacrine in doses of 10 mg per rat daily for 3 days. After 70% hepatectomy the remaining hepatocytes very rapidly lost their glycogen and basophilic cytoplasmic granules; currently eosinophil spheres appeared in the cytoplasm and increased in size and number during the first 6 hr. These bodies stained for acid phosphatase activity; they apparently resulted from the aggregation of lysosomes. As seen under the electron microscope many of these structures contained degraded cytoplasmic organelles, glycogen rough endoplasmic reticulum, and mitochondria. After starvation (24 hr.) followed by 70% hepatectomy, starvation itself reduced the glycogen and basophilic granules; the hepatectomy did not bring about any further changes. Surface alterations did occur. Inj. of actinomycin D at the time of 70% hepatectomy completely abolished the mitotic response to the hepatic ablation. However, the cytoplasmic response to 70% ablation did occur. Forty-five percent hepatectomy produced no noteworthy effect. Inj. of chloroquine and quinacrine appeared to increase the size of the autophagosomes.

2 THE EFFECT OF HYDROCORTISONE ON THE SPEED OF DETOXIFICATION OF ETHANOL. (Ger.) Fischer, H.-D. (Med. Acad. "Carl Gustav Carus," Dresden, Germany). *Biochem. Pharmacol.* 15(7):785-791, 1966.

Two groups of adult rabbits of both sexes received pretreatment for 5 days with hydrocortisone (cortisol), 5 and 10 mg, resp., s.c. twice daily. In the first group, the speed with which toxic doses of ethyl alcohol were eliminated from the system was increased by more than 60%; in the second, it was increased by 90%. In rabbits receiving 5 mg of cortisol (s.c. twice daily) for 6 days, the mean liver content of niacin amide adenine dinucleotide was increased from 452 to 471 μ g/g, as compared to controls; the mean liver content of the same substance in reduced form decreased from 255 to 157 μ g/g; the mean ratio of the 2 was increased from 1.7 to 2.8. Mean liver lactic acid content was increased from 110 to 413 μ g/g; mean pyruvic acid content, from 9.7 to 42.5 μ g/g; the mean ratio of the 2 was decreased from 5.6 to 9.8. It is concluded that the influence of cortisol on the speed of elimination of ethyl alcohol may be related to these phenomena and/or to a possible, unidentified effect on lipid metabolism.

3 VARIATIONS IN GLUCURONIDE FORMATION BY PERINATAL LIVER. (E.) Dutton, G. J. (Queen's Coll., Dundee, Scotland). *Biochem. Pharmacol.* 15(7):947-951, 1966.

Mouse and rats, fetal and infant, were investigated for activity in liver homogenates of the microsomal "detoxifying" enzyme, UDP-glucuronyltransferase (UDP-GT), using o-nitrophenol, p-nitrophenol, and phenolphthalein as acceptor substrates and the sodium salt of UDP glucuronic acid as donor substrate. Conjugates measured in liver homogenates occurred only in the presence of UDP glucuronic acid; these conjugates were hydrolyzed by β -glucuronidase only and were therefore presumably glucuronides. Maternal hepatic tissue which shows no particular change in UDP-GT activity was used for controls. Some UDP-GT activity arose in the mouse as early as days 14 and 15 of fetal life with phenolphthalein and o-aminophenyl as acceptor substrates; the activity increased toward birth, being about 20% with o-nitrophenol and 86% with phenolphthalein. In the first few days after birth there was roughly a 20% increase over the initial values at birth. In perinatal rats activity developed more rapidly toward p-nitrophenol than towards phenolphthalein as acceptor substrate; the activity toward p-nitrophenol decreased and increased toward phenolphthalein until these separate activities approached each other about 5 days after birth. During the first few postnatal days, the values in the rat for o-nitrophenol were much greater than in the adult liver, being about 200% on the first day, declining to about 140% on day 5.

- 9754 BIOCHEMICAL EFFECTS OF PREDNISOLONE ON HUMAN LIVER CELLS IN TISSUE CULTURE. (E.) Pihl, A. (Norsk Hydro's Inst. Cancer Res., Oslo, Norway) and P. Eker. Biochem. Pharmacol. 15(7):769-777, 1966.

All experiments were carried out on adult human liver cells (Chang) grown in monolayer cultures. Cell counts were taken using a particle counter. Analyses were made for protein, glucose and glycogen. Hexokinase and glucokinase activities were determined, and assays done for glucose-6-phosphatase and fructose-1,6-diphosphatase. The growth inhibiting effect of prednisolone on human liver cells in monolayer cultures was most pronounced during the first few hr. of incubation; almost coincident with growth inhibition was increased glycolysis. Prednisolone in 125- μ M conc., which completely inhibited cell multiplication during the first 3 hr. had no effect on the concurrent incorporation of C^{14} -labeled thymidine into DNA and of C^{14} -methionine into proteins. The incorporation of C^{14} -orotic acid into RNA was slightly reduced at a 250- μ M conc. of the steroid. The glycogen content of the cells was increased after incubation with prednisolone for 20-30 hr. Experiments with labeled glucose indicated that the extra glycogen was not derived from glucose. The incorporation of labeled pyruvate was not affected by prednisolone, whereas the steroid increased the incorporation of radioactivity from labeled alanine. No effect of prednisolone was found on the levels of activity of hexokinase, glucokinase, glucose-6-phosphatase, and fructose-1,6-diphosphatase.

- 9755 KINETICS OF (1- ^{14}C) PALMITATE UPTAKE AND INCORPORATION INTO LIPID FRACTIONS OF LIVER SLICES. (E.) Vavrecka, M. (Inst. Human Nutrition, Prague, Czechoslovakia), R. Poledne and R. Petrusek. Biochim. Biophys. Acta 125(1):176-178, 1966.

Liver slices (180-195 mg) were incubated in Krebs-Ringer phosphate (Ca ion omitted) in O_2 at 37° C. After 10 min. 0.3 ml of 1- C^{14} palmitate in a complex with albumin was added. At intervals from 2.5 to 120 min. the incubation was terminated; after careful washing to remove all medium, the slices were extracted with a mixture of chloroform and methanol. The lipids were separated by thin layer silicic acid chromatography; subsequently the monoglycerides were separated from the phospholipids by ether. Radioactivity of total lipids and individual lipid fractions was determined by a scintillation counter. After 120 min. of incubation over 40% of the radioactivity originally present in the medium was incorporated into the total lipids of the tissue; two phases of this intake of labeled palmitate were apparent. In Phase 1, during the first 5 min. the rate of uptake was high. The following numerical values were the rates in mEq/g wet wt./hr.: a) uptake into total lipids 14.5; b) esterification of palmitate, 3.75; c) incorporation into fatty acid fraction, 10.4. Of the total uptake 26.5% was esterified. In Phase 2, during the last 90 min. of the experiment, the rate of uptake was much less; the numerical values were, resp.: a) 2.45, b) 2.10 and c) 0.35. Eighty-six percent of the palmitate was esterified during this period. The rate of uptake into the different lipid fractions was in decreasing order: (1) free fatty acids, (2) 1,2-diglycerides, (3) triglycerides, (4) monoglycerides, (5) cholesterol and 1,3-diglycerides, (6) cholesterol esters.

- 9756 RAT LIVER TRIGLYCERIDE LIPASE. (E.) Olson, A. C. (U. Oklahoma Sch. Med. Oklahoma City) and P. Alaupovic. Biochim. Biophys. Acta 125(1):185-187, 1966.

Acetone-dried powders or fresh liver homogenates were extracted with 0.1 M phosphate buffer, pH 7.2; the extract was further fractionated by gentle shaking with an equal vol. of 4° C n-butanol. When the phases were allowed to separate, the interfacial fluff contained the lipolytic activity; this layer was removed and washed with acetone. The standard assay system consisted of equal vol. of enzyme extract from the acetone dried preparations or the fresh homogenates mixed with an equal vol. of substrate comprising 7 parts of 0.1 M phosphate buffer, pH 7.2, 1 part of 4% deoxycholate, 1 part 50% coconut oil emulsion, or 1 part 10% emulsion of olive oil stabilized by 2% gum arabic. The mixed enzyme-substrate system was incubated at 37° C; activity was recorded by measuring release of fatty acids. The protein content of the enzyme preparation was determined. Specific activity of the enzyme was expressed as μ M of fatty acid released 1 hr./mg protein. The

rate of hydrolysis of emulsified olive oil was proportional to the amount of enzyme in the enzyme preparation. The optimal pH was 7.2 with another peak at 7.8-8.0. Testing these enzyme-substrate systems with and without sodium taurocholate, it was found that lipolytic activity was increased several times in the presence of the bile salt. Albumin produced a sharp decrease in activity. Diethyl-p-nitrophenyl phosphate in aqueous soln. had no effect; however, emulsion of E-600 caused a 50% inhibition. This lipolytic activity indicates the presence in liver tissue of glycerol ester hydrolase. No activity is shown with aqueous soln. of methylbutyrate as substrate.

7 FURTHER EVIDENCE ON THE HEPATIC SITE OF ACTION OF THE HORMONE SECRETIN. (E.) O'Maille, E. R. L. (U. Liverpool, England), T. G. Richards and A. H. Short. *J. Physiol.* (London) 185(2):76P-77P, 1966.

Infusion of a secretin extract at a constant rate of 0.2 U/kg body wt./min. in anesthetized dogs in which the common bile duct was cannulated and the cystic duct ligated led to substantial increases in bile flow rate but had no effect on the maximum excretory rate of sulfobromophthalein (SBP). Increases in bile flow rate of the same order following taurocholate admin. at constant rate caused marked reduction of the maximum excretory rate of SBP. The secretin preparation was compared by the method of Crick, Harper, and Roper (1949) and contained some bile salt, but this amount was not sufficient to contribute to the bile flow rate changes experienced. The results indicate that the hydrocholeretic action of secretin is exerted at a point downstream from the canaliculi since choleresis originating in the bile ducts would not influence the maximum excretory rate of SBP.

8 AUDIORADIOGRAPHIC STUDY OF PROLIFERATIVE PROCESSES IN THE HISTOGENESIS OF THE LIVER IN RATS (Rus.) Gratcheva, N. D. (Cent. Res. Inst. Roentgenol., Min. Health USSR, Moscow). *Ark. Anat.* 50(5):38-46, 1966.

Parallel autoradiographic studies were conducted on proliferative processes in hepatic parenchymal and hematopoietic cells of 15- and 18-day-old rat embryos and those of 1-day-old and 3- to 16-day-old rats. The label used was H³-thymidine, given s.c. as single or repeated doses of 0.5-1.0 μ C/g to mature and newborn rats, or of 5-10 μ C/g into the placenta or directly into the embryo. On days 15 and 18 of embryogenesis, almost all hepatocytes and hematopoietic cells were found to be in the process of proliferation, whereas at birth, half of the hepatocytes had ceased to divide. In the first few hr. after H³-thymidine, an increase was noted in the number of labeled hepatocytes and hematopoietic cells, but the labeled mitosis method yielded only an approximate reflection of the generation time of the 2-cell populations. There was no substantial change in the length of the hepatocyte cycle from day 15 of embryogenesis to the first postnatal day, and slight lengthening of the phase of DNA synthesis observed in the newborn rats may be connected with changes in the external conditions encountered by the organism or with functional stress on the liver. Although no definite conclusions can be drawn from these findings on extramedullary hematopoiesis, possible hypotheses are that hepatocytes and hematopoietic cells have an almost identical cycle; that two populations--one with a short, and one with a long, cycle--make up the hematopoietic cells; or that the hematopoietic cell cycle is shorter than that of the hepatocytes.

9 PERFUSION OF THE ISOLATED CANINE LIVER IN VIVO AND IN VITRO. (E.) McLaughlin, E. D. (Harvard Med. Sch., Boston, Mass.) and W. G. Austen. *Trans. Am. Soc. Artif. Intern. Organs* 12:259-264, 1966.

In vivo dog liver perfusions of 5 hr. duration demonstrated a progressive decrease in hepatic blood flow, beginning after the second hr. with a progressive increase in hepatic artery blood pressure when the perfusate was a nonpulsatile blood flow, whereas a pulsatile blood flow maintained an adequate vol. of blood flow at normal pressures of hepatic artery blood pressure. In addition, in vitro dog liver perfusions of the same time period showed that the decrease in the blood flow vol. seen during nonpulsatile blood flow was associated with a decrease in venous pH, a decrease in venous pO₂ and an increase in venous pCO₂. When pulsatile blood flow was employed for in vitro liver perfusions, the blood flow was maintained adequately for 15 hr. and the venous pH, pO₂ and pCO₂ remained at acceptable levels.

HEPATIC METABOLISM

- 9760 QUANTITATIVE DISTRIBUTION OF LACTIC DEHYDROGENASE IN THE REGENERATING LIVER LOBULE OF THE RAT. (E.) Thaler, M. M. (Hosp. Sick Children, Toronto, Ontario, Canada) and J. M. Kissane. J. Histochem. Cytochem. 14(6):495-500, 1966.

Qualitative studies of rat liver regeneration during the 30 hr. following a partial hepatectomy revealed a depletion of glycogen from portal and midzonal regions, accumulation of fat in the periportal zones and heavier conc. of lactic dehydrogenase (LDH) in peripheral areas of the regenerating lobule. Quantitative studies showed that the LDH activity was 40-50% higher in the peripheral zones than in the central zones. Activity was intermediate in the midzonal regions, except for the 30-hr. sample which approached the conc. of the portal zones. Similar levels and relative conc. of LDH persisted throughout the time investigated. Periportal DNA conc. increased by about 30% during the regenerative stage, while centrilobular conc. remained unchanged and only a slight increase was seen in the midzone. Staining for fat revealed a heavy conc. of lipid material confined entirely to the peripheral area, while glycogen was found in relatively larger quantities in parenchymal cells of the central zones.

- 9761 PERFUSION IN SITU WITH TRITIUM OXIDE TO MEASURE HEPATIC LIPOGENESIS AND LIPID SECRETION. NORMAL AND OROTIC ACID-FED RATS. (E.) Windmueller, H. G. (NIH, Bethesda, Md.) and A. E. Spaeth. J. Biol. Chem. 241(12):2891-2899, 1966.

The combined use of tritium oxide and in situ rat liver perfusions permitted rate determinations for hepatic fatty acid and cholesterol biosynthesis as well as net secretion of newly synthesized fat. With livers from rats fed 1% orotic acid for 5 days or more, a net uptake of perfusate fatty acids occurred; whereas a large net release of triglycerides occurred in normal livers. All livers added cholesterol and phospholipid to the perfusate, although the quantity was significantly less when animals had been treated with orotic acid. With livers from orotic acid-fed rats, incorporation of H^3 into liver fatty acid was 21% of control values and only very small quantities were detected in the perfusate. From whole animal (rat) studies with i.v. Triton WR-1339, the block to lipid secretion was found to increase in severity during the first wk. of orotic acid feeding; a drop to 67% of normal, and accumulated liver triglyceride were seen only after 3 days of continuous feeding. The lipid block was rapidly reversed by inclusion of 0.25% dietary adenine sulfate.

- 9762 EFFECTS OF ACTINOMYCIN D ON BASE COMPOSITION AND NEAREST NEIGHBOR FREQUENCY OF NUCLEOLAR RNA OF THE WALKER TUMOR AND LIVER. (E.) Ro, T. S. (Baylor U. Coll. Med., Houston Tex.), K. S. Narayan and H. Busch. Cancer Res. 26(5):780-785, 1966.

Male rats were used in a series of experiments on the base composition of RNA in the nucleoli and extranucleolar regions of the nuclei in the liver of rats and the Walker 256 carcinosarcoma with and without inj. of actinomycin D (150 μ g/kg body wt.). Radioautographs were also prepared from liver and tumor sections taken from rats inj. with actinomycin D- C^{14} . Isolation of nucleoli and of nuclei without nucleoli was accomplished by sonic vibration followed by layering in sucrose soln. in the centrifuge. After this the separated nucleoli and nuclei were precipitated and washed. The precipitate was hydrolyzed and the percentages of individual nucleotides calculated after separation by chromatography and measurements of optical density at the wavelength of max. absorption. The effect of actinomycin was a decrease in the content of cytosine and an increase in the ratio of adenine + uracil over guanine + cytosine in the nucleolar RNA of the liver. The results in the tumor were not marked. Isolated nucleoli were incubated with substituted, labeled ATP and guanosine triphosphate for studies of radioactivity in the nearest neighbor frequencies. These were different in the liver from those in the tumor indicating a suppression by actinomycin of synthesis of high molecular wt. guanine-cytosine-rich RNA. The radioautographic studies revealed a greater suppression of nucleolar synthesis than of extranucleolar synthesis. This was more marked in the liver than in the tumor.

TIC METABOLISM

THE EFFECT OF ACTINOMYCIN D ON ULTRASTRUCTURE AND RADIOAUTOGRAPHIC RIBONUCLEIC ACID AND PROTEIN LABELING IN RAT LIVER AFTER PARTIAL HEPATECTOMY. (E.) Stenram, U. (U. Uppsala, Sweden) and R. Willén. Cancer Res. 26(4):765-772, 1966.

Rats weighing 80-85 g were admin. i.p. inj. of 0.06 mg of actinomycin D/100 g wt. Later the same day they underwent two-third hepatectomy to stimulate and protein synthesis. The animals were nourished by s.c. inj. of glucose and amino acid soln. Next day the rats were inj. s.c. with 5 μ C L-leucine- H^3 or with 5 μ C cytidine H^3 /g body wt. The animals were killed 30 min. or 3 hr. later. Liver sections were prepared for the electron microscope and also for the optical microscope. Control animals, not inj. with actinomycin, were otherwise prepared in the same way. The nucleoli of actinomycin-treated animals were much smaller than nucleoli in controls, and as a rule were collapsed, but retained the three components a and b (also termed the nucleolonema and the large granules) and the electron-lucent areas. The non-nucleolar portions of the nucleus were more homogeneous in the control. In actinomycin-treated rats the interchromatinic granules were often prominent and ring-shaped inclusions were observed in some nuclei. Grain counts of the radioautographs showed decreased RNA labeling in actinomycin-treated animals especially over nucleoli and cytoplasm. As judged from ribonuclease-treated sections, there was virtually no DNA labeling either in controls or in experimental animals. According to the grain counts, the protein labeling over the nucleoli seemed to be decreased but was unchanged over the parts of the cell. It should be emphasized that the changes described were obtained with high doses of actinomycin which practically extinguished the nucleolar RNA labeling.

ENZYMES OF GLUCOSE-6-PHOSPHATE METABOLISM IN DENERVATED LIVER. (Rus.) Shanygina, K. I. (Inst. Exp. Med., USSR Acad. Med. Sci., Leningrad). Vop. Med. Khim. 12(3):258-261, 1966.

Studies on the role of the 2 enzymes catalyzing the phosphorylation of glucose in the mammalian liver, the activities of the aspecific enzyme, hexokinase, and the specific enzyme, glucokinase, and of glucose-6-phosphate dehydrogenase and glucose-6-phosphatase were determined in the liver of male rats and cats 3 wk. after partial denervation and resultant partial blocking of afferent nervous impulses. In microsomes from partially denervated livers, there was a 50% decrease in glucose-6-phosphatase activity and a marked increase (200%) in hyaline plasma glucose-6-phosphatase activity, accompanied by a significant decrease in specific glucokinase activity and a corresponding increase in aspecific glucokinase (hexokinase) activity. After glucose (6 ml i.p. of a 5% soln. 3 times/24 hr.) nor insulin (8 U i.m. 3 times/24 hr.) restored the specific glucokinase activity lowered by partial denervation. This lack of response apparently reflects a disruption of structural and chemical organization in the livers of the experimental animals.

THE SPECIES SPECIFICITY OF CHOLESTYRAMINE IN ITS EFFECT ON SYNTHESIS OF LIVER LIPIDS AND LEVEL OF SERUM CHOLESTEROL. (E.) Gallo, D. G. (Mead Johnson Res. Ctr., Evansville, Ind.), R. W. Harkins, A. L. Sheffner, H. P. Sarett and W. M. Cox, Jr. Proc. Soc. Exp. Biol. Med. 122(2):328-334, 1966.

Young male rats were maintained on basal diet for two wk. and then separated into 13 groups of 10 rats each. Four groups were fed the basal ration; 9 groups received the same basal diet containing 2% cholestyramine, an insoluble quaternary ammonium ion exchange resin, which has a strong affinity for bile acids; it also increased fecal elimination of neutral sterols. After 4 wk. cholestyramine was withdrawn from the diet of 3 of the groups. During a 7-wk. study period, groups of animals were sacrificed at intervals. Cockerels (4-wk.-old) were separated into groups of 10 each and treated in the same manner as the groups of rats. The cockerels fed on basal diet with 2% cholestyramine showed no marked effect on plasma or liver cholesterol levels. Addition of acetate- C^{14} after 2 days of cholestyramine treatment indicated greatly increased lipid synthesis which continued to increase for 10 days. On withdrawal of cholestyramine rapid reduction in lipid synthesis was observed. Liver homogenates of resin-treated animals showed significant increase in cholesterol synthesis within 24 hr. of onset of treatment. Removal of the resin from

HEPATIC METABOLISM

the diet decreased sterol synthesis by homogenates within 24 hr. In the chicken the plasma level of cholesterol was reduced but the liver level was not changed by the cholestyramine in the diet. Chicken liver homogenates from birds having the resin in the diet showed increased sterol synthesis but of lesser magnitude than in the rat.

- 9766 NICODIN AS A CHOLAGOGUE. (Rus.) Skakun, N. P. (Ternopol Inst. Med., USSR) and A. N. Oleinik. *Vrach. Delo* (6):63-64, 1966.

Nicodin (pyridine-3-tricarboxylic acid hydroxymethyl amide) is a derivative of nicotinamide and formaldehyde and owes its antibacterial action to the latter group and its regenerative effect on hepatic function to its amide moiety. Its cholagogic action was studied in acute experiments on 42 mice and 5 dogs with various types of artificial gallbladder fistulas. In doses of 5-10 mg/100 g, Nicodin progressively increased bile secretion in rats by an av. of 37.7% over the 4-hr. observation period; larger doses (50 and 100 mg/100 g) led to still greater increases: 40.6 and 44.9%, resp. In dogs, increased bile secretion was generally apparent after 30, to (usually) 60 min. after Nicodin admin., and stimulation was usually max. in hr. 2-3. Nicodin also enhanced the excretion of bile acids and other inorganic and organic substances with the bile. It did not affect the tonus of the biliary ducts. Although definitely cholagogic and choleretic, Nicodin was only 20% as potent in this respect as dehydrocholic acid.

- 9767 THE EFFECTS OF ADRENALECTOMY AND HYPOPHYSECTOMY ON BILE FLOW IN THE RAT. (E.) Bauman, J. W., Jr. (New Jersey Bureau Res., Princeton), B. S. Chang and F. R. Hall. *Acta Endocr. (Kobenhavn)* 52(3):404-408, 1966.

Hypophysectomized and normal female rats were prepared with special bile duct cannulas (polyethylene tubing) allowing collection of bile or its return by means of a U-tube. Rats were lightly anaesthetized before collections were made to allow manipulation of the tubing; rats were lightly restrained during collections. Av. bile flow in 9 hypophysectomized rats (0.2-0.3 ml/100 g/hr.) was found to be half or less that of the normal rat (0.5-0.6 ml/100 g/hr.). Neither corticosterone (200-400 µg/day) or DOC (1 mg/day) increased the flow in hypophysectomized rats. Adrenalectomy did not reduce flow up to 14 days after surgery. A repeat of the adrenalectomy experiment with a different strain of rat yielded the same results. It is concluded that the decreased flow of bile following hypophysectomy does not involve the adrenals.

- 9768 QUANTITATIVE ANALYSIS OF ULTRASTRUCTURAL COMPONENTS OF NUCLEOLI OF THE WALKER TUMOR AND LIVER. (E.) Smetana, K. (Baylor U. Coll. Med., Houston, Tex.), K. S. Narayan and H. Busch. *Cancer Res.* 26(5):786-789, 1966.

Male rats (180/250 g) were sacrificed 15 hr. after partial hepatectomy and other animals, admin. i.p. inj. of thioacetamide (50 mg/kg body wt./day) or at specified times, were killed 9 days after first inj. Still others received 1 inj. of 150 µg/kg body wt. of actinomycin D 1 hr. prior to killing. The Walker 256 carcinosarcoma used in these studies was excised 6-8 days after transplantation. Sections of liver from experimental and control animals and from the Walker tumor were prepared for electron microscopy. Fibrillar and granular areas of nucleoli were measured on electron micrographs by planimetry and expressed as % of total nucleolar area. Areas containing fibrillar components measured: normal liver, 19 ± 4 ; regenerating liver, 12 ± 3 ; liver, thioacetamide inj., 4.5 ± 0.3 ; liver, actinomycin inj., 48 ± 23 ; Walker tumor, 3 ± 2 . Granular areas made up most of the remainders. The same result as for the Walker tumor was found in immature cells of a plasmacytoma, lymphatic leukemia, and monocytic leukemia. It is suggested that the fibrillar areas contain an RNA fraction rich in adenylic and guanylic acids.

- 9769 EFFECTS OF NORETHYNODREL AND PROGESTERONE ON HEPATIC MICROSOMAL DRUG-METABOLIZING ENZYME SYSTEMS. (E.) Juchau, M. R. (U. Iowa, Iowa City) and J. R. Fouts. *Biochem. Pharmacol.* 15(7):891-898, 1966.

Male rats (80-100 g) were maintained on standard laboratory food, quickly killed, the livers placed on ice, blotted and weighed. For each gram of liver 2 ml of ice cold

ATOMIC METABOLISM

5% KCl was added and the mixture homogenized and centrifuged at 9000 times gravity at low temperature. Studies were carried out on the supernatant fractions. In some cases the animals were treated before sacrifice with progesterone and nandrolone (NE). The steroids were suspended in 1% carboxymethylcellulose, and admin. i.p. or p.o. When animals were pretreated with these steroids only the metabolism of zoxazolamine (Z) and hexobarbital (H) was affected in vitro. Both agents were capable of inhibiting the metabolism of those drug substrates when admin. i.p. prior to sacrifice of the animals. NE stimulated the metabolism of H when admin. 18 and 48 hr. before sacrifice. Metabolism of H was also stimulated after acute and chronic pretreatment with NE. Pretreatment with NE produced a stimulation of Z when admin. between 18-36 hr. prior to sacrifice. Stimulation was also observed after chronic admin. of NE. Pretreatment with progesterone did not produce any stimulation of H or Z metabolism. When NE or progesterone were added directly to incubation mixtures containing the liver supernatant, appropriate cofactors and drug substrates, so that the conc. of the steroid was 10^{-5} or 10^{-4} M, side-chain oxidation of H, ring hydroxylation of Z and the p-hydroxylation of amine were inhibited. To a lesser degree, the steroids also inhibited the ring hydroxylation of 3,4-benzpyrene and N-demethylation of aminopyrine. They did not appreciably affect the reduction of the nitro radical of p-nitrobenzoic acid, the reduction of the azo linkage of neoprontosil, the o-demethylation of codeine or the metabolism of chlorpromazine.

STIMULATION OF POLYAMINE SYNTHESIS IN RELATION TO NUCLEIC ACIDS IN REGENERATING RAT LIVER. (E.) Raina, A. (U. Helsinki, Finland), J. Jänne and M. Siimes. *Biochim. Biophys. Acta* 123(1):197-201, 1966.

The rats (2 and 3 mo. old) were 2/3 hepatectomized by removal of the median and lateral lobes. The animals used as controls were sham operated 16 hr. before sacrifice. At the time of analysis the rats were sacrificed under anesthesia. The livers were quickly removed and chilled on crushed ice, then homogenized in 9 times vol. of ice water. Equal vol. of homogenate and 10% trichloroacetic acid were added and the polyamines in the supernatant analyzed by the amido black method. Nucleic acids were extracted from the precipitate and analyzed and the nucleic acid content of the livers calculated. In a second group of hepatectomized rats labeled methionine was inj. at 4, 8, 12 and 16 hr. postoperatively. Analysis was performed 16 hr. after inj. Radioactivity was measured in a liquid scintillation spectrometer for separation of the polyamines and proteins by paper chromatography. Partial hepatectomy caused an early stimulation of spermidine synthesis as indicated by the increased increase in the incorporation of labeled methionine into this polyamine as early as 4-8 hr. after operation. At 16 hr. the specific activity of spermidine in experimental animals was 10 times that of the sham-operated controls. The total spermidine content was significantly elevated at 16 hr. and at 64 hr. it was 10 times that of the controls. The specific activity of spermine, on the other hand, did not increase until 16-20 hr. and the total amount of spermine per liver showed no increase until 64 hr. after partial hepatectomy. The total amount of RNA was significantly increased at 32 hr. and the total amount of DNA at 64 hr. The ratio of polyamine nitrogen to RNA phosphate remained quite constant during liver regeneration. It is possible that tissue polyamines act as stabilizers of nucleic acids, especially RNA.

EFFECT OF PROTEIN DEPLETION AND SUBSEQUENT REPLETION IN RATS AT DIFFERENT AGE PERIODS. II. CHANGES IN BLOOD AND LIVER. (E.) Radhakrishnan, M. R. (Nutrition Res. Lab., Hyderabad-7, Pakistan). *Indian J. Med. Res.* 54(5):494-500, 1966.

Two lots of 60 rats each, half male, half female, 4 wk. old, were subdivided. Lot 1 was subdivided into 2 groups, again with equal distribution of male and female animals, a distribution which was continued throughout all subdivisions. Group 1 was maintained on control diet for the duration of the experiment; Group 2 was depleted of protein between the 4th and 8th wk.; at the end of the 8th week 6 animals were sacrificed, and also at the end of the 9th, 10th, 11th and 12th wk. Lot 2 was subdivided into equal Groups 3, 4, and 5. Group 3 received a control diet during the entire period of study. Group 4 was depleted of protein between the 12th and 16th wk.

HEPATIC METABOLISM

Group 5 received no protein in the diet during 2 periods: between the 4th and 8th wk. and between the 12th and 16th wk. At all other times the animals received the control diet. Four animals from each of these groups were sacrificed at the end of the 16th, 17th, 18th, 19th and 20th wk. Rats were individually caged. Before killing the rats, blood was collected by cardiac puncture, and the liver removed under anesthesia. Hb, serum total protein, and albumin were estimated. Wet wt. of liver was obtained. Nitrogen content and succinic dehydrogenase (SD) activity were determined. Hb was determined as oxyhemoglobin, protein by sulfite fractionation and micro Kjeldahl; nitrogen by macro Kjeldahl, and SD by the Thunberg technic. These various factors all showed decreases following protein depletion. Protein depletion between the 4th and 8th wk. resulted in relatively greater depression of these values than did protein depletion between the 12th and 16th wk. However, depletion at an earlier age had no effect on the response of these animals to protein deprivation between the 12th and 16th wk. On repletion all values returned to normal, although protein deprivation between the 4th and 8th wk. required a longer time for regeneration, than between the 12th and 16th wk.

9772 EFFECTS OF TWELVE COMMON FATTY ACIDS IN THE DIET UPON THE COMPOSITION OF LIVER LIPID IN THE RAT. (E.) Caster, W. O. (U. Georgia, Athens), H. Mohrhauer and R. T. Holman. *J. Nutr.* 89(2):217-225, 1966.

Male weanling rats were divided into 21 groups of 6 rats each. Each group was fed the basal fat-free Mohrhauer-Holman diet plus the ethyl esters of the supplemental oil equal to 10% of the total calories. Dietary fatty acid ethyl ester mixtures were prepared from common fats and oils plus small amounts of purified fatty acid esters. The compositions of these mixtures were adjusted to allow independent but simultaneous study of 12 of the dietary fatty acids; each one of the mixtures of ethyl esters was fed to 1 of the groups of rats for 66 days, when the rats were killed and the livers were stored in saline soln. at -20°C until they were analyzed for fatty acids; the fats were extracted and interesterified using 2% sulfuric acid in absolute ethanol. The resulting esters were quantitatively analyzed by gas chromatography. Metabolic interactions and interconversions were indicated by intercorrelations calculated with the aid of digital computers. Equations for estimating the amounts of 4 dietary fatty acids from the analysis of liver tissue, and of 7 tissue fatty acids from an analysis of the diet are presented. The linolenate requirement of the rat is estimated from these latter equations to be 0.14% of the caloric intake. There are high diet-tissue correlations between acids of the linoleate family and between acids of the linolenate family. The amounts of certain saturated and monoenoic fatty acids in the diet had marked effect on these correlations. The usual view that an increase in the amount of any fatty acid in the diet will result in a corresponding increase in this fatty acid in liver tissue is true for certain lipids as, 14:0, 16:1, 18:2, 18:3 and 20:1; however, there were zero or negative correlations between dietary and tissue conc. of 16:00, 18:00 and 18:1. Dietary oleic acid shows little positive correlation with the conc. of any of the liver fatty acids. The conc. of oleic acid in the liver is controlled by several factors.

9773 REACTIVE CHANGES IN LIVER TISSUES UNDER CONDITIONS OF AUTOTRANSPLANTATION IN AMPHIBIA AND MAMMALS. (Rus.) Filimonova, G. F. (Leningrad Sanit-Hyg. Inst., USSR). *Arkh. Anat.* 50(6):19-20, 1966.

In 2-3 yr.-old frogs (*Rana temporaria*; total about 300) portions (2-3 mm) of liver were transplanted to the abdominal lymphatic sac and to striated muscular tissue, while in adult random-bred albino mice or mice of strain C₃HA (total 120) under the skin, to adipose tissue and to the femoral striated muscle. The transplantants (T) were studied after 1 hr.-6 mo. Most of the autotransplanted tissue in mice died, only the marrow zone of cells on the periphery of the segment remained vital; in later stages T consisted almost completely of newly formed gland cells. T in frogs showed only small amounts of necrotization; in later stages T consisted both of newly formed (by division) and old preserved liver cells. Dystrophic changes in mice and frogs were similar, but in the latter they were less pronounced and developed over a longer period of time. In early stages of damage a general tendency toward a decrease and redistribution of RNA, total protein, glycogen, alkaline phosphatase,

ATIC METABOLISM

cinic dehydrogenase were noted. The activity of acid phosphatase, lipase and amount of fatty inclusions was increased. Later the cells became more regular in appearance. For the later stages part of the hepatic cells in mice (especially random bred) died, and changes occurred in cellular reaction of hepatocytes in the frogs. In the mice the appearance of antibodies to heterogenic tissue even in conditions of an autogenous organism played a definite role. Also in the later stages many plasma cells and lymphoid cells accumulated in the transplant and around it. In both frogs and mice, mitoses appeared on day 10, and continued for 1.5 mo.; the bile ducts showed better survival and a conversion of bile duct epithelia into hepatic cells was not observed. The reaction of connective tissue to T in frogs was slight; however, in mice, especially the random bred, the connective tissue actively reacted against T and appeared more diverse.

- 4 BILIRUBIN, BROMSULPHTHALEIN AND INDOCYANINE GREEN EXCRETION IN BILE. (E.) Hargreaves, T. (St. George's Hosp. Sch. Med., Hyde Park Corner, London). Quart. J. Exp. Physiol. 51(3):184-195, 1966.

The addition of sulfobromophthalein (BSP) to rat liver slices or rabbit liver homogenates inhibits the conjugation of bilirubin and o-aminophenol in both cases. The addition of indocyanine green inhibits conjugation in rabbit liver homogenates only, which suggests that its metabolic pathway prior to excretion is slightly different from that of BSP. The addition of BSP to phosphate-bicarbonate solution containing conjugated bilirubin reduced the uptake of the latter by normal or heat-denatured liver slices. In vivo, BSP reduced the maximum hepatic clearance of bilirubin, but bilirubin did not have the same effect on BSP clearance, indicating that the latter is excreted in the bile in preference to bilirubin. In contrast, when bilirubin and indocyanine green are administered simultaneously, the biliary excretion of the latter is decreased. Simultaneous administration of BSP and indocyanine green again showed a differential excretion of BSP.

- 5 HEPATIC SYNTHESIS OF ALPHA₂ (ACUTE PHASE)-GLOBULIN OF RAT PLASMA. (E.) Sarcione, E. J. (Roswell Park Mem. Inst., Buffalo, N. Y.) and A. E. Bogden. Science 153(3735):547-548, 1966.

Plasma perfusing isolated rat livers in vitro the incorporation of leucine-H³ into a protein which was precipitated with a rabbit antiserum (specifically directed against rat alpha₂ (acute phase)-globulin) increased with time over 3 hr. in animals showing acute inflammatory reaction to injury. Acute inflammation was produced by daily s.c. inj. of 1.0 ml of commercial-grade steam distilled wood turpentine for 3 days before livers were removed. These data indicate that the liver is a source of alpha₂ (acute phase)-globulin and the appearance of this protein in the serum reflects de novo synthesis by the liver rather than release of preformed and stored protein. These data also agree with the proposal that hepatic synthesis of this serum component is stimulated by factors released into the blood from injured or necrotic tissue.

- 6 AUTOREGULATION OF HEPATIC CIRCULATION. (E.) Takeuchi, J. (Kanazawa U. Sch. Med., Japan), T. Kitagawa, T. Kubo, I. Murai and T. Tone. Jap. Heart J. 7(2):168-180, 1966.

Using isolated dog liver perfused with homologous blood (cross-matched and diluted with saline to an average hematocrit of 17.8%), autoregulation was demonstrated in the hepatic artery system. When the portal vein pressure (PVP) was kept at about 10 mm Hg and the hepatic artery pressure (HAP) was successively raised in a stepwise fashion from 30-260 mm Hg, the hepatic artery flow (HAF) was increased proportionally less than the rise in HAP within a range of approximately 80-160 mm Hg. This indicates that the hepatic artery resistance (HAR) was raised as the HAP increased. In contrast, such autoregulation was not demonstrated in the portal vein system. Here, the portal vein flow (PVF) was increased proportionately or more than the rise in PVP when HAP was held constant at approximately 100 mm Hg. Thus the pulmonary vascular resistance (PVR) was unchanged or decreased as the PVP increased. Study of the interaction of the two systems showed that an increased HAP produced a slight increase in PVR, while an increase in PVP gave little effect on HAR.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 9826 A COMPARATIVE ASSESSMENT OF VARIOUS METHODS OF DIAGNOSING DYSENTERY IN CHILDREN. (Rus.) Ruzaikina, N. I. (Pirogov 2nd Moscow Med. Inst., USSR). Vop. Okhr. Materin. Dets. 11(4):22-26, 1966.

The comparative value of various diagnostic methods is assessed on the basis of observations on 316 children with dysentery, aged -1 to 3+ yr., seen in the early stage of their illness from 1963-1965. The percentage of positive results was highest (86.8% of 129 children) with the serum agglutination test, but the value of this reaction is more retrospective than immediately helpful. In 82.1% of the 205 children so tested, the intradermal test with dysentery allergen was positive (by day 3 to 4), as against bacteriologic confirmation of dysentery in only 49.2% of this same group. The skin reaction was particularly conspicuous in the older children. As for the rise in phage titer, this reaction was positive in only 20.5%, phenomenon explained by the existence of a substantial number of phage-resistant dysentery cultures.

- 9827 ROLE OF THE TYPE OF PERSONALITY IN THE RESPONSE TO ENDOSCOPIC EXAMINATIONS (Cz.) Horackova, E., V. Brodan and A. Culik. Cesk. Gastroent. Vyz. 20(2):139-142, 1966.

Rectoscopic examination was done in 36 patients, and gastroscopy in 12 patients who were previously evaluated psychologically. No premedication was given prior to rectoscopy; 1 hr. prior to gastroscopy, the patients received an inj. of morphine with atropine and shortly prior to gastroscopy, tetracaine tablets for local analgesia. There was no correlation between the spastic reaction and the index of neuroticism of these patients. However, there was a striking positive relationship between a poor tolerance of these examinations and infantile features of personality, hysterical symptoms, and depressive moods (particularly in the cases of rectoscopy, where paradoxically the patient anxiety was greater than in the gastroscopy cases). Individual psychotherapeutic approach and premedication are stressed for the prevention of spasms.

- 9828 DIPHENIDOL, A NEW ANTIEMETIC: A DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY. (E.) Small, M. D. (District of Columbia Gen. Hosp., Washington, D. C.). Am. J. Dig. Dis. 11(8):648-651, 1966.

Thirty patients experiencing nausea and vomiting due to uremia, metastatic cancer, liver diseases, or various other reasons were selected for the double-blind study. The severity was rated and each patient was admin. 6 ampules and 50 capsules. Patients with severe nausea and vomiting who didn't respond within 1 1/2-2 days were admin. known antiemetics. Diphenidol was given in initial doses of 20-40 mg i.m., followed by oral doses of 25-100 mg every 4-6 hr. After each dose the medication was rated for its effect on nausea and vomiting, and at the end of the study it was rated according to its relief of symptoms and onset of action. Diphenidol was significantly more effective than the placebo for relief of both nausea and vomiting as it was for overall performance. Ten of 15 patients receiving placebo were not relieved from nausea and vomiting, and were placed on other antiemetics, whereas only 1 of 15 on diphenidol failed to obtain relief. Five patients had side effects, 2 on placebo and 3 on diphenidol. Diphenidol did not cause side effects that can occur with phenothiazines. In higher doses diphenidol was useful in controlling 1 case of intractable singultus.

- 9829 EVALUATION OF KATO'S THICK SMEAR TECHNIC WITH A CELLOPHANE COVER FOR HELMINTH EGGS IN FECES. (E.) Komiya, Y. (NIH, Tokyo) and A. Kobayashi. Jap. J. Med. Sci. Biol. 19(1):59-64, 1966.

Kato's thick smear technic for counts of helminth eggs in feces makes use of cellophane, not waterproof, about 40 microns thick, cut to the size of 26 by 28 mm in place of glass coverslips. The cellophane slips are soaked for at least 24 hr. before use in a soln. composed of 1 liter of 50% glycerine in water to which 5 ml of 3% aqueous malachite green soln. is added. The strong light under which the slides are examined is made comfortable by the green dye. The glycerine provides a clearer differentiation of the eggs. The fecal specimen, about 65 mg, is placed

AGNOSTIC PROCEDURES AND GENERAL THERAPY

a slide and covered with a pretreated, wet cellophane slip which is pressed down that a thick stool film is formed between the slide and the cover. The slide preparations are kept at room temperature for 30 min. to become more translucent making the eggs easier to detect. The slides are examined under the microscope at a magnification of 100. Kato's technic was compared to 3 other methods for pinth eggs: the usual thin smear technic employing glass covers; flotation in saturated salt soln.; and Harada-Mori's culture method. Fecal specimens (175) from different individuals known to be infected with hookworm were each tested by the 4 methods. The thin smear technic yielded only 18.3% positive; Kato's technic, 52.6% positive; flotation test, 64.7% and the culture method, 79.6%. The thick smear technic was almost 3 times more reliable than the thin one, about 12% below the flotation test, and 27% below the culture method. Kato's technic is especially suited to mass testing; it is rapid, inexpensive and technically simple.

- 30 NONSUTURE INTESTINAL ANASTOMOSIS. (E.) Weilbaecher, D. A. (Louisiana State, New Orleans), C. T. Stirling and F. J. Mathieu. Bull. Soc. Int. Chir. 25(2):125-136, 1966.

dogs the usage of 3 different plastic adhesive substances to perform nonsuture testinal anastomoses proved successful in 113 cases and failed in 46. The anastomosis was completely separated in only 13 instances in these 46 failures, while in the remaining 33 the separation was partial. The following types of everted end-to-end anastomoses were done: 130 at approx. 15 cm proximal to the ileocal valve, 8 in the mid-descending colon and 1 within the duodenum. Inverting anastomoses were performed in 20 animals; of which 9 were gastrojejunostomy and 11 were enteroenterostomy. In the latter group, 89% of the anastomoses were satisfactory, whereas with the everting type the percentage was 69. Examination of disrupted edges failed to reveal any instance of extensive necrosis. There was no significant difference in the results of the 3 types of adhesives. The results indicated that this technic is still unsatisfactory for clinical application.

GASTROINTESTINAL DISEASES

GENERAL

- 9862 MULTIPLE MYELOMA INVOLVING THE GASTROINTESTINAL TRACT. (E.) Goldstein, W. B. (Rockefeller U. Hosp., New York, N. Y.) and N. Poker. Gastroenterology 51(1):87-93, 1966.

A 52-yr.-old man was demonstrated to have multiple myeloma. Roentgen findings included a persistent large defect in the duodenum; multiple defects were found in the jejunum and ileum. In spite of therapy the patient died 43 days after admission. At autopsy gross examination of the digestive tract showed numerous gray white nodules, most of which were centrally ulcerated; a nodule in the stomach measured 3 cm across and was perforated. Microscopically these nodules were composed of densely packed immature myeloma cells.

- 9863 THE EFFECT OF LEAD, BENZENE AND ALPHA-METHYLSTYRENE ON THE RATE OF RADIOACTIVE METHIONINE INCLUSION IN THE PROTEINS CONTAINED IN DIFFERENT PORTIONS OF THE GASTROINTESTINAL TRACT. (Rus.) Braginskaia, L. L. (Inst. Hygiene, Ufa, USSR) and V. A. Sukhanova. Gig. Tr. Prof. Zabol. 10(5): 26-30, 1966.

One of the many possible approaches to the multiple etiology of diseases of the gastrointestinal tract is exploration of the effects of industrial poisons. Here, the effects of 3 such poisons were studied in rabbits, by comparing the rate of incorporation of S^{35} -labeled methionine into the mucosal proteins of various regions of the digestive tract in poisoned and control animals. Chronic lead poisoning was induced by introducing 5 ml/kg of a 1% soln. of lead acetate (0.003 g lead) into the stomachs of rabbits every other day for 1 mo. Subacute benzene and α -methylstyrene poisoning was induced by daily s.c. inj. of 1 ml/kg of a 4:1 soln. of the toxin in peach oil for 5 days. In the digestive mucosa of control rabbits sacrificed after i.m. inj. of S^{35} -methionine, radioactivity was highest in the proteins of the pancreas, next highest in those of the duodenum, and higher in the lesser curvature than in other parts of the stomach. In rabbits subjected to chronic lead poisoning, methionine incorporation was most conspicuously enhanced in the proteins of the small intestinal mucosa, and after subacute poisoning with benzene or α -methylstyrene, methionine incorporation in the mucosal proteins was depressed throughout the gastrointestinal tract, especially in the pyloric segment of the stomach and in the pancreas.

- 9864 LABORATORY Vibrio cholerae INFECTION IN THE UNITED STATES. (E.) Sheehy, T. W. (Walter Reed Army Med. Ctr., Washington, D. C.), H. Sprinz, W. S. Augerson and S. B. Formal. J.A.M.A. 197(5):321-326, 1966.

Two cases of accidental V. cholerae infection are reported, the first cases of cholera recorded in the U.S. since 1911. Both men, laboratory technicians, presumably became infected from laboratory cultures of V. cholerae. Stool isolates were positive. The antigenic strain originally in the laboratory was Inaba which suddenly changed in V. cholerae isolates from the first patient to the Ogawa strain. There was no desquamation of intestinal mucosa although bioptic specimens taken from both patients were hyperemic and the jejunal villi of Case 1 appeared swollen. On admission patient 1 complained of thirst, weakness and watery stools. Vital signs were normal. There were no physical signs of dehydration. The patient was afebrile. Forced fluids by mouth were begun immediately. Blood physical chemical factors were within accepted normal limits. Tetracycline therapy was very effective. On admission patient 2 complained of abdominal cramping, diarrhea, weakness, and severe generalized headache. He appeared to be acutely ill. His tongue and oral mucosa appeared dry. Serum specific gravity was 1.030 (normal, 1.025). Parenteral fluid therapy was initiated immediately, and during the first day the patient received a total of 5000 ml of 5% dextrose in normal saline with 50 mg of KCl added. The next day 2% $NaHCO_3$ was also given to maintain the electrolyte conc. In the first 24 hr. the patient lost 2,350 ml in 22 watery, alkaline stools and excreted 2,100 ml of clear urine. Stool cultures were negative the first day after oral tetracycline therapy.

ERAL

5 HISTOPATHOLOGY OF THE UPPER SMALL INTESTINES IN TYPHOID FEVER. BIOPSY STUDY OF EXPERIMENTAL DISEASE IN MAN. (E.) Sprinz, H. (Walter Reed Army Ctr., Washington, D. C.), E. J. Gangarosa, M. Williams, R. B. Hornick and T. E. Woodward. Am. J. Dig. Dis. 11(8):615-624, 1966.

healthy male prison inmates were voluntarily challenged with an oral dose of $\times 10^9$ organisms of an 18-hr. culture of Salmonella typhosa, the strain of which had been isolated from a human carrier. It was admin. in milk after a 3-hr. fast and no medication was given until clinical illness developed. Chloramphenicol was then given in a dose of 3 g immediately, followed by 1 g every 8 hr. To rule out intestinal change due to this drug, 3 other subjects received the chloramphenicol in comparable doses for a longer period and exhibited normal biopsies. Biopsy specimens were obtained by the method of Crosby and Kugler. Tissue was obtained from each subject prior to challenge, shortly after challenge or as soon after convalescence as could be tolerated, and during convalescence. Postchallenge biopsies showed enteritis in all subjects, indicating involvement of upper small intestine even in the absence of lymph follicles in the specimen. The enteritis affected the epithelial lining of the villi, crypt glands, and the tunica propria. Histologic alterations of the intestinal mucosa were not associated with clinical symptoms. A granulomatous reaction of the tunica propria was present only in the subjects who developed typical typhoid fever with leukopenia. The enteritis was reversible in all subjects leaving no sequelae, and the convalescence biopsy was comparable to the control biopsy. Healing occurred without antimicrobial therapy in the 2 mild cases; while chloramphenicol aided histologic restitution in the 4 severe cases.

6 DEMONSTRATION OF PROTEIN-LOSING GASTROENTEROPATHY. THE DISAPPEARANCE RATE OF ^{51}Cr FROM THE PLASMA AND THE BINDING OF ^{51}Cr TO DIFFERENT SERUM PROTEINS. (E.) Van Tongeren, J. H. M. (U. Nijmegen, The Netherlands) and C. L. H. Majoor. Clin. Chem. Acta 14(1):31-41, 1966.

^{131}I -labeled proteins or their degradation products were measured in the intestinal contents or feces after i.v. inj. of the labeled substances using a scintillation counter with a sodium iodide crystal as a detector. Other compounds usually employed for this purpose are ^{131}I -albumin and ^{131}I polyvinylpyrrolidone (^{131}I -PVP). PVP is excreted by the salivary glands and is readily reabsorbed through the wall of the gut, whereas Cr^{51} , released by proteolytic digestion in the gut, is not absorbed; it does not normally enter the gastrointestinal lumen. Another difficulty is encountered in the use of ^{131}I -PVP, the molecular wt. of which averages 40,000-400,000, but some batches have smaller molecular wt. with the result that 90% of ^{131}I -PVP dosage may be lost in the urine in 2 days. There is a decline in radioactivity of plasma following i.v. inj. of Cr^{51} and ^{131}I compounds even in persons who are not losing plasma proteins through the wall of the digestive tract. There are two chief reasons for this: first, dispersal of radioactive compounds in extravascular fluid compartments, and second, the continuing loss through urinary excretion (25-35% of the dosage within the first 5 days), aided by the degradation of plasma proteins, mostly albumin and transferrin to which Cr^{51} is bound. The decline in radioactivity is very rapid in the first days after inj. After 6 days the curve follows a constant exponential course. The rates of plasma loss of Cr^{51} after i.v. inj. of Cr^{51} -serum, Cr^{51} -albumin, and $\text{Cr}^{51}\text{Cl}_3$ are essentially the same. It is concluded that there is no advantage in the use of Cr^{51} -albumin over $\text{Cr}^{51}\text{Cl}_3$ which is simpler to use and is less costly. The Cr^{51} becomes bound to plasma albumin and β -globulin.

7 DEMONSTRATION OF PROTEIN-LOSING GASTROENTEROPATHY. THE QUANTITATIVE ESTIMATION OF GASTROINTESTINAL PROTEIN LOSS, USING ^{51}Cr -LABELLED PLASMA PROTEINS. (E.) Van Tongeren, J. H. M. (U. Nijmegen, The Netherlands) and W. J. Reichert. Clin. Chim. Acta 14(1):42-48, 1966.

Loss of protein through the gastrointestinal wall can be quantitatively determined from the plasma radioactivity disappearance curve after inj. of 8.5 ml of 40 μC ^{51}Cr taken up in 10 ml 0.9% NaCl (1.5 ml reserved for a standard). Following i.v. inj. of the dose, blood samples are withdrawn into heparinized test tubes at 5, 15, 20, and 25 min. and at intervals of several hr. during the first day. Two

GENERAL

samples are taken on each of the next 5 days. Radioactivity of the 3 ml samples is measured in a scintillation counter. The resulting data are plotted on a linear scale, radioactivity in cpm on the ordinate and time on the abscissa. The area under the curve to the time T is represented by $\int_0^T A_p(t) \cdot dt$. From this the ml of plasma completely freed of marked protein/min. is calculated, multiplied by 60×24 , the clearance in ml/day. A second graph is plotted semilogarithmically with radioactivity against time. The experimental curve is resolved into 3 ST line components. The required parameters can be read from the graph and the value L calculated. L equals the clearance of labeled protein caused by leakage through the intestinal wall, expressed in ml of plasma/min. In 16 normal cases the values derived from the 2 methods were quite close. In 14 normal cases the av. clearance was 13 ml/day (range 2-23 ml). In patients with elevated intestinal permeability or with high central venous pressure, clearances up to 600 ml/day have been found.

9868

ENTEROMEGALY AND STEATORRHEA IN THE RAT FOLLOWING INTRAPERITONEAL QUINACRINE (ATABRINE). (E.) Keeler, R. (U. Newcastle upon Tyne, England) H. Richardson and A. J. Watson. Lab. Invest. 15(7):1253-1262, 1966.

Large doses of quinacrine (10 mg daily for 5 days) admin. i.p. to rats produced a marked abdominal distention within 1-3 wk. which was caused by pronounced enteromegaly chiefly affecting the cecum. The ileum and proximal colon are also affected but to a lesser extent. By day 10, the cecum is at least 3 times larger than normal. The mean wt. of the small and large intestines of 8 quinacrine-treated rats were, resp., 2.3 and 4.0 times greater than normal. Associated with this gross enlargement is the failure of water absorption from the cecal contents and retention of solids, steatorrhea and reduction of food intake to the point of emaciation. Pieces of gut removed from quinacrine-treated rats 28 days after the first inj. showed little spontaneous motility; the response of cecum and colon to $0.2 \mu\text{g/ml}$ of acetylcholine was much diminished. The response of a normal ileum *in vitro* to the same dose of acetylcholine was also greatly reduced by 0.01 mg/ml of quinacrine, while 10 times that abolished normal spontaneous motility.

9869

THE IMPORTANCE OF ANTIBODIES AGAINST MILK PROTEINS IN GASTROINTESTINAL DISTURBANCES AND OTHER DISEASES OF INFANCY. (It.) Bardare, M. (U. Milan, Italy) and P. Regine. Minerva Pediat. 18(14):743-744, 1966.

Serum antibodies against milk proteins were found in 253 (38%) of 661 infants (most unweaned) screened with hemagglutination tests (Boyden's method as modified by Sewell); 66% of 248 patients with dyspepsia, but none of the 3 patients with celiac disease, had antibodies. Serum antibodies were found in a significant number of children with bronchopneumonia (46 of 84) and bronchial asthma (18 of 42); most of these positive patients also had associated eczema. In only 11% (19 patients) of 166 patients with non-allergic conditions were antibodies demonstrated. The majority of antibodies were against β -lactoglobulin and casein; those against lactalbumin were less frequent. Serum titers ranged from 1/20 to 1/5120; the highest titers were found in unweaned infants with protracted and recurrent enteritis or dyspepsia. Immunoprecipitation tests in agar (Ouchterlony method), done in half the patients, were almost all negative, as were 25 cutaneous passive anaphylaxis tests in guinea pigs. The authors conclude that, although sensitization to milk proteins occurs more frequently than was perhaps thought, the presence of antibodies, especially in low titer, does not necessarily mean a true allergy to milk, but may signify only that undigested milk proteins have reached the circulation, perhaps secondary to lesions of the intestinal mucosa.

9870

EXPERIMENTAL CHOLERA IN THE RABBIT LIGATED ILEAL LOOP: TOXIN-INDUCED WATER AND ION MOVEMENT. (E.) Leitch, G. J. (U. Chicago, Ill.), M. E. Iwert and W. Burrows. J. Infect. Dis. 116(3):303-313, 1966.

Ileal loops (about 30 cm long) were prepared in 16-wk.-old rabbits fasted for 24 hr after flushing out the lumen of this section with sterile saline. A sterile saline soln. (5 ml) of dried cholera toxin, whole cell lysate, was inj. into the loop; in control animals sterile saline only was inj. The dried cholera toxin was derived from heavy suspensions of *V. cholerae* 569B in distilled water, ultrasonically disrupted, and then centrifuged; the supernatant was freeze-dried yielding the powdered toxin. The animals were sewn up and allowed to recover from

operation. At various periods after the operation experimental and control animals were killed by a blow to the back of the neck; left ventricular blood samples were taken; the contents of the loop were removed, the vol. measured, and the fluid centrifuged to remove cellular material. Loop tissue was also removed for histological examination and for determination of water content. Osmotic pressure of plasma and loop fluid was measured by the freezing point depression. Protein analysis was by the biuret method. Analyses by appropriate means were done for Na, K, Mg, Cl and bicarbonate in both plasma and loop fluid. Water content of the serosal wall was determined as well as the potential difference between mucosal and serosal surfaces in some animals. Diamox was also admin. to some animals in the drinking water. After a 4-hr. latent period the fluid accumulation progressed at constant rate dependent upon the conc. of the toxin inj. The plasma reflected its fluid loss with increased osmotic pressure and an eventual decreased plasma conc. Bicarbonate appeared to be actively secreted into the loops, whereas chloride was absorbed to maintain electroneutrality. The Na conc. of the loop fluid was initially the same as that of the plasma but as the vol. of loop fluid increased loop fluid Na to plasma Na ratio exceeded unity. The carbonic anhydrase inhibitor Diamox decreased the net water flux into the loop and as a result decreased the net loss from the plasma of all types of ions after admin. of toxin. The only ionic species to show differences in conc. in loop fluid between Diamox-treated and untreated animals were bicarbonate and Cl, bicarbonate decreasing 11 mEq and Cl increasing 14 mEq/liter with the drug. The potential difference was always serosal side positive to mucosal surface.

71 PROTECTION OF MONKEYS AGAINST EXPERIMENTAL SHIGELLOSIS WITH A LIVING ATTENUATED ORAL POLYVALENT DYSENTERY VACCINE. (E.) Formal, S. B. (NIH, Bethesda, Md.), T. H. Kent, H. C. May, A. Palmer, S. Falkow and E. H. LaBrec. *J. Bact.* 92(1):17-22, 1966.

Virulent strains of *Shigella flexneri*, 1b, 2a, and 3, and *S. sonnei* 1 were mated with an Hfr strain of *Escherichia coli*. Hybrid clones were purified and their biochemical patterns determined. A single hybrid strain from each cross was selected. Tested in starved guinea pigs, the virulence of the hybrid strains was much reduced over the virulence of the parent strains. The ability of the hybrid strains to penetrate the epithelium was not lost, and a mild acute inflammatory reaction ensued. The parent strains remained in the small intestine over the course of the experiment, whereas the hybrid strains were rapidly cleared from the small intestine. Keratoconjunctivitis in guinea pigs was severe when caused by the parent strains and milder when caused by the hybrid strains which retained the capacity to enter HeLa cells in tissue cultures. Each of the hybrid strains agglutinated in its resp. typing serum. A single dose fed to monkeys did not produce diarrhea in 1 wk. Two doses of polyvalent oral vaccine composed of hybrid strains of *S. flexneri* 1b, 2a, and 3, and *S. sonnei* 1 with *E. coli* were fed to groups of monkeys at an interval of 4-7 days; 10 days after the second dose these groups together with controls were challenged with one or another of the virulent parent dysentery strains. A significant degree of protection was afforded in all vaccinated groups with the exception of 1 group challenged with *S. flexneri* 6, a component not included in the vaccine. When animals were challenged with virulent *S. flexneri* 2a 1 mo. after oral vaccination, they were still protected. The vaccine produced a rise in serum antibody, but proantibody was not detected.

72 THE 1964 EPIDEMIC OF TYPHOID FEVER IN ATLANTA. CLINICAL AND EPIDEMIOLOGIC OBSERVATIONS. (E.) Collins, R. N. (Communicable Dis. Ctr., Atlanta, Ga.), W. M. Marine and A. J. Nahmias. *J.A.M.A.* 197(3):179-184, 1966.

An outbreak of typhoid fever occurred in Atlanta in Aug. and Sept., 1964, involving 11 individuals, only one of whom was an adult; there was 1 death, a 4-yr.-old girl, and 1 case of relapse, a 13-yr.-old boy. All patients were members of 3 households in the same neighborhood, cousins and friends; attack rates for the children in the households were 53, 50, and 20%. All attempts to trace the source of the infection proved unsuccessful. Careful investigation of water, sewage, streams in the neighborhood, food sources, kitchens, and bathrooms proved negative for *Salmonella phi* as did the surveys of family members and contacts. Typhoid vaccine was admin.

to adults and children early in the outbreak. Multiple positive blood cultures for *S. typhi* E₁ confirmed the diagnosis in 13 patients. The diagnosis of typhoid fever in 2 cases was made on the basis of positive stool cultures. The frequency of positive blood cultures was striking when compared to number of positive stool cultures of the 13 children with positive blood cultures, only 6 subsequently had positive stools. The initial WBC was usually within normal range but the differential was remarkable for the presence of 13-34% band forms in 10 patients. Salmonella group D agglutination reactions were elevated in 12 patients on admission. Follow-up serologies 6 mo. after onset of the illness were negative except for the relapsed case who still had an H titer positive at 1:80. Fourteen received antimicrobial therapy; 13 received chloramphenicol; 1 patient received ampicillin for 6 days after which therapy was changed to chloramphenicol. Duration of fever following initiation of therapy ranged from 1-9 days with a mean of 5 days. One patient also received a short course of corticosteroids. The initial difficulty in diagnosis of typhoid fever is the wide range of symptomatology coupled with the fact that few physicians have seen a case of typhoid.

9873 STUDY OF LIGATED RABBIT-GUT SEGMENT AND ITS CONTENTS AFTER INTRODUCTION OF *V. cholerae* AND ITS CULTURE-FILTRATE. (E.) Dutt, A. R. (Infect. Dis. Hosp., Calcutta-10, India). *Indian J. Med. Res.* 54(5):431-436, 1966.

Pure cultures of smooth Ogawa or Inaba strains of *Vibrio cholerae* were inj. into intestine segments, created by ligatures 10 cm apart, in the rabbit. The animal was killed 24 hr. later and the distended loop dissected out; the contents were collected in a sterile test tube, the vol. measured, the appearance noted, and the fluid measured. The loop was then split open along the mesenteric line and fixed in 10% formaldehyde-saline. Specimens obtained from the upper, middle and lower portions were prepared for microscopic examination; stains were hematoxylin and eosin. Similar tests using closed intestinal loops were made on a total of 14 animals which were killed at 3, 6, 9, 12 and 24 hr.; control loops were collapsed and empty. At 3 hr., test loops were collapsed and empty; beginning at hr. 6 there was progressively an increased fluid accumulation in the closed loops until the max. vol. was reached at 24 hr. In a similar manner the fluid became increasingly hemorrhagic with time. The histologic changes also were of a progressive nature, marked at first by swelling of villi; edema, vascular dilatation and lymphatic engorgement. The mucosa and submucosa were infiltrated by polymorphonuclear leukocytes and lymphocytes. Goblet cells were prominent. Submucosa became edematous. The lining epithelium began to slough. Denudation became widespread. Eosinophils and plasma cells appeared. Using the same technics employed with live *Vibrio* cultures, a culture-free filtrate containing enterotoxin was inj. into isolated gut segments. The minimum effective dose (MED) of the enterotoxin was established as the smallest amount of enterotoxin which will give a positive loop response. Multiple MED (1,2,4,8) were inj. into prepared intestinal loops; these were examined at 6, 9, 12, and 24 hr. Control loops were collapsed and empty. An examination of the results from the series of cholera enterotoxin tests revealed that these were almost identical with the results obtained in the series of tests using live cultures. The changes encountered with the live cultures at 12 hr. resembled those seen with 8 MED of enterotoxin at 24 hr.

9874 PATHOGENESIS OF EXPERIMENTAL CHOLERA: IDENTIFICATION OF CHOLERAGEN (PROCHOLERAGEN A) BY DISC IMMUNOELECTROPHORESIS AND ITS DIFFERENTIATION FROM CHOLERA MUCINASE. (E.) Finkelstein, R. A. (SEATO Med. Res. Lab., Bangkok, Thailand), P. Z. Sobocinski, P. Atthasampunna and P. Charunmethe. *J. Immun.* 97(1):25-33, 1966.

The production of choleragen (I), its bioassay in infant rabbits, and its immunologic assay by the Outcherlony technic have been described in a previous paper. I so produced was studied in terms of its action in producing experimental cholera and also its apparent concomitant mucinase activity which was tested upon carefully prepared ovomucin in a standardized procedure with a definite mucinase unit. Preliminary steps in the purification of the I not only increased its choleragenic activity but also enhanced the mucinase activity. Rabbit antiserum against crude I neutralized the mucinase activity of the purified I. In addition, electrophoretic

NERAL

udies showed that the band identified as I was in the same region of the acryl-
ide gel as the 7S gamma globulin band of human serum and was considered an entity.
ese findings led to the opinion that both activities were properties of the same
olecule. However, disc immunoelectrophoresis of purified I revealed multiple pro-
in staining components. Very careful differential precipitation by ammonium sul-
te resulted in the separation of the choleraemic substance from the enzyme, con-
rmed by bioassay, mucinase determinations, disc immunoelectrophoresis and quanti-
tative Outcherlony assays. Further work on skin sensitivity indicated that the
oleraemic principle is responsible for vascular dilatation, and increased capil-
ry permeability resulting in edema at the site of inoculation. Mucinase produc-
on, by 24 strains of V. cholerae in the three categories, classical, El Tor, and
n-agglutinable, showed a wide variation in titer from 0 to 1024 and apparently
correlated with I production.

- 75 MATERNAL AND OTHER FACTORS IN THE ETIOLOGY OF INFANTILE COLIC. REPORT OF
A PROSPECTIVE STUDY OF 146 INFANTS. (E.) Paradise, J. L. (Bellair
Clin., Ohio). J.A.M.A. 197(3):191-199, 1966.

Incidence and intensity of colic in a group of 146 infants was studied with re-
spect to possible correlation with (1) maternal emotional factors: overall psycho-
logical disturbance, anxiety, rejection of the feminine or maternal role, and lack of
energy and enthusiasm; (2) maternal experience, intelligence, and education; and
(3) other family factors such as the economic class and paternal occupation. A re-
view is presented of previous ideas and suggestions concerning the etiology of
colic. The present study was carefully followed through with special interviews,
and tests (Minnesota Multiphasic Personality Inventory) which were machine-scored
and computer analyzed to evaluate maternal emotional factors. Significant colic
developed in 23% of 146 normal newborn. Its incidence was unrelated to family
economic class, maternal age, birth order, sex, wt. gain, type of feeding, or family
history of allergic or gastrointestinal disorder. Superior maternal intelligence
and advanced maternal education seemed associated with a higher than av. incidence
of colic, possibly because of better maternal reporting or lower maternal tolerance.
The occurrence of colic showed no relationship to maternal emotional factors,
whether estimated clinically or measured by a standardized psychological test.
Most mothers of infants with colic were stable, cheerful and feminine. This and
other evidence when critically reviewed does not support the frequently stated view
that colic results from an unfavorable emotional climate created by an inexperienced,
anxious, hostile or unmotherly mother.

- 76 HISTOPATHOLOGICAL STUDIES ON EXPERIMENTAL CHOLERA. (E.) Patnaik, B. K.
(U. Edinburgh Sch. Med., Scotland) and H. K. Ghosh. Brit. J. Exp. Path.
47(3):210-214, 1966.

The introduction of Vibrio cholerae into ligated rabbit intestinal loops (starting
about 40 cm from the ileo-cecal junction and proceeding upwards) produced fluid
accumulation which progressively worsened. By hr. 12 the 10-cm loops were
distended with 5-10 ml of fluid and patches of hemorrhage appeared in the serosal
surface. By 18 hr. the loops were gangrenous. Electron microscopic studies at
12 hr. revealed minute pyriform vesicles in the plasma membrane of the microvilli,
with rupture of some vesicles so that the core of the villi communicated with the
lumen. The mitochondria became irregular in shape and opaque; the cytoplasm was
relatively opaque too. Substances of low electron density fill spaces under the
epithelial basement membrane, which is thus separated from the lamina propria;
while at the same time, the capillary endothelial cells do not overlap at their
edges, widening the spaces between them. Both of these factors would allow fluid to
escape from the blood vessels into the perivascular spaces (at a far greater rate
than with pinocytotic transport), which could explain the mechanism of fluid
accumulation.

- 77 HISTOCHEMICAL EVALUATION OF ENZYMATIC ACTIVITIES IN PLEOMORPHIC SALIVARY
ADENOMA. (E.) Murata, I. (Osaka U. Sch. Dent., Japan) and T. Miyaji.
Oral Surg. 22(1):82-90, 1966.

Pleomorphic salivary gland adenomas were surgically removed from parotid glands (7

GENERAL

cases), the palatal region (4 cases), the buccal mucosa (1 case) and the upper lip (1 case) and specimens were tested for localization of enzymatic activity. Alkaline phosphatase activity was absent in the neoplastic elements except for a moderate reaction in capillaries and in inflamed areas. Acid phosphatase, β -esterase and β -glucuronidase were distributed in the acinar neoplastic epithelium. Succinic dehydrogenase reacted moderately in neoplastic cells, while DPN-dependent lactic and malic dehydrogenase activities were notably present in this glandlike tissue. TPN-dependent glucose-6-phosphate and isocitric dehydrogenase activities were confined to epithelial elements. Stromal connective tissue was almost lacking in enzymatic activity. The pattern of enzymatic reactions in this tumor was similar to that of ductal cells in normal salivary glands. In addition, the majority of these tumors exhibited an acinar or ductal structure containing solid clumps or columns of epithelium.

- 10052 THE MECHANISM OF VASOPRESSIN HEMOSTASIS IN BLEEDING ESOPHAGEAL VARICES. AN ANGIOGRAPHIC STUDY IN THE DOG. (E.) Aronsen, K. F. (U. Lund, Sweden) and G. Nylander. Acta Chir. Scand. 131(5):443-453, 1966.

Seventy-two angiographic examinations were performed before and 5 min. after admin. of vasopressin in 40 mongrel dogs deprived of food for 18 hr. Arterial splanchnic contrast blood flow was studied by performing aortography in 9; selective arteriographies of superior mesenteric artery in 1; selective celiacographies in 7. Portographies were performed in 5 dogs in which portal vein and transhepatic contrast blood flow could be studied. To obtain esophageal varices on which vasopressin action could be studied, 14 dogs were subjected to portal vein ligation and 4 to common bile duct ligation. The 16 survivors had portographies performed to study the portosystemic communications. Four dogs failed to develop any coronary-esophageal collaterals. Of the 12 others, 7 developed both true submucosal esophageal varices and paraesophageal collaterals, while in 5 dogs only the latter were obtained. The effect of vasopressin on arterial splanchnic contrast blood flow showed that after admin. the distribution to hepatic and renal arteries increased while that to other branches of the abdominal aorta decreased. The action on celiac artery showed that the distribution to splenic and gastric arteries decreased while that to the hepatic artery increased. Angiography of the superior mesenteric artery and its tributaries showed a decreased contrast-blood velocity and dilation of larger vessels with vasopressin. Portography showed a decreased velocity of transhepatic contrast blood flow and dilation of portal vein and its intrahepatic branches. Portography also showed that true submucosal esophageal varices are not visualized, but paraesophageal collaterals are dilated after admin. of vasopressin. The vascular response to vasopressin was uniform throughout all experiments. In addition to the generally accepted theories of the hemostatic effect of vasopressin an additional explanation of its effect may be its action on smooth esophageal musculature, resulting in a bypass of the submucosal esophageal varices by the portosystemic blood flow.

- 10053 ACID-BARIUM SWALLOWS IN THE RADIOGRAPHIC EVALUATION OF CLINICAL ESOPHAGITIS. (E.) Donner, M. W. (Johns Hopkins Hosp., Baltimore, Md.), M. L. Silbiger, P. Hookman and T. R. Hendrix. Radiology 87(2):220-225, 1966.

Twenty patients (10 with symptoms of esophagitis and a positive acid perfusion test and 10 normal with a negative acid perfusion test) were studied with simultaneous cineradiography and manometric monitoring of intraluminal pressure employing 4 transducers with a train of catheters having their tips spaced 5 cm apart and a 4-channel recorder. Conventional barium suspension, and acid barium suspension were used. After positioning the patient, a peristaltic wave initiated by a single swallow of barium was observed as it traversed the entire length of the esophagus. One swallow following another prematurely can cause interruption of the initial peristaltic wave. An uninterrupted peristaltic wave is recorded on the motion picture film as the intraluminal pressure sequence is graphed on the 4-channel recorder. The same procedure was used with acid barium. After recording several acid barium swallows the patient received a tablespoonful of antacid preparation. All 10 patients with symptoms of esophagitis had a positive acid barium test; i.e., the esophagus responds to acid barium with periods of aperistalsis and nonperistaltic contractions lasting for 20 to 30 seconds associated with regurgitation and delayed emptying and terminating in a peristaltic wave. All 10 normal patients had a negative acid barium test; i.e., their esophageal peristaltic waves were the same as with conventional barium suspension. Eighty-one other cases with clinical diagnoses of esophagitis were studied by X-ray motion picture without pressure recording. Most of these had a normal peristaltic response to normal barium preparation but with acid barium showed segmented nonperistaltic contractions. Of these 81, 80 showed a disturbed esophageal motility. Of 23 additional patients without symptoms of esophagitis only 1 had a positive acid barium test.

ESOPHAGUS

- 0054 TREATMENT OF ACHALASIA OF THE CARDIA. (E.) Nanson, E. M. (U. Saskatchewan, Saskatoon, Canada). Gastroenterology 51(2):236-241, 1966.
Expanding-bag dilation is cited as the method of choice for treating cardiospasm, as it can be done under local anesthesia with little discomfort to the patient and with great financial saving in comparison to the Heller operation. A literature survey indicates that at least 75% of the patients are ameliorated by dilation. However, the Heller operation is indicated for children under 12 yr. of age, patients with sigmoid esophagus, patients with suspected malignancy and patients who relapse after an adequate trial (3 attempts) of dilation. When the dilation is done it must be forceful and excessive in order to tear the offending muscle fibers; it must be done under fluoroscopic control and local anesthetics. For the latter, 10 mg of Pantopon and 0.4 mg of scopolamine s.c. 1 hr. before as premedication, and 50-100 mg of meperidine HCl i.v. just before the procedure plus application of 5% tetracaine HCl to the mouth and pharynx is recommended. The author's version of the Heller operation is described in detail.
- 0055 THE AIR ESOPHAGRAM: A SIGN OF SCLERODERMA INVOLVING THE ESOPHAGUS. (E.) Dinsmore, R. E. (Massachusetts Gen. Hosp., Boston), D. Goodman and J. R. Dreyfuss. Radiology 87(2):348-349, 1966.
Chest X-rays of 16 patients (with definitely established scleroderma involving the esophagus as proved by barium esophagrams in 15 cases and by autopsy in case 16) were reexamined with the result that the presence of air was found in the intrathoracic portion of the esophagus in 12 of the 16 cases. The air esophagram was most frequently seen in the distal esophagus and then best shown on the lateral view. Seven of the 12 positive cases showed characteristic pulmonary changes which the authors regard as virtually specific for this condition. The dysfunction of smooth muscle in scleroderma involving the esophagus is reflected in the diminished peristalsis and limited collapsibility found on barium swallow examination. It is not surprising therefore that an air esophagram is present on the routine chest roentgenogram.
- 0056 ELECTIVE TREATMENT OF BLEEDING ESOPHAGEAL VARICES. (E.) Gordon, H. E. and G. Glantz. Curr. Probl. Surg. 1966:4-13.
Esophageal bleeding occurred in 118 of 132 patients with Laennec's cirrhosis. Of these 118, 104 (88%) died within a yr. Upon examination, 42 of 45 patients with Laennec's cirrhosis had esophageal varices seen by esophagoscopy and further confirmed by upper gastrointestinal X-ray examination to rule out gastroduodenal lesions as the source of bleeding. Cirrhotic patients require special preoperative care. The degree of operative risk can be assessed using the classification of Wantz and anyone: Group A, patients with good hepatic reserve; Group B, patients with moderate hepatic disease; Group C, patients with advanced hepatic disease. The criteria for, and the limits of, these groups are defined in the paper; the reported operative mortality was 4.4% (Group A), 10.4% (Group B), and 47.4% (Group C). The choice of type of operation seems to be portacaval shunt, side-to-side, or end-to-side; at times a splenorenal shunt is useful. The postoperative mortality for elective shunts for the years 1950-1965 was 12 deaths among 80 patients operated upon.

(Gastric ulcer is placed with peptic ulcer)

- 10122 THE EFFECT OF ATROPINE-N-n-OCTYLBROMIDE AND GASTRIC ACIDITY LEVEL. (Ger.) Gromotka, R. (U. Erlangen, Germany) and W. Fahsold. Arzneimittelforschung 16(6):766-768, 1966.

Atropine-N-n-octylbromide, 0.01 mg i.v., induced a shift of pH in the direction of alkalinity in 14 of 16 patients with gastric hyperchlorhydria and a pH of 3.0 in 3 of 16, lasting 10-18 min. Doubling the dosage resulted in significant reduction gastric acidity in all 11 patients, with pH values of more than 3.0 lasting 50-380 min. in 6 of 11. Admin. of 0.02 mg i.m. increased the pH above 3.0 in 9 of 11 patients, with a duration effect of 20-300 min. Peroral admin. of the same dose resulted in pH above 3.0 in only 3 of 11, with a duration of 30-220 min. Side effects included dry mouth, tachycardia, palpitation of the heart, headache, fatigue, nausea and difficulty in ocular accommodation. All were transient and none were sufficient to make patients reluctant to continue medication.

- 10123 THE EFFECT ON AUTONOMIC FUNCTIONS OF [γ (β -HYDROXYETHYLPIPERAZINO)-PROPYL]-5-H-DIBENZO-[b,f]-AZEPINE-DIHYDROCHLORIDE (OPIPRAMOL). (Ger.) Hammerl, H. (Wilhelmina Hosp., Vienna, Austria) and O. Pichler. Arzneimittelforschung 16(6):748-754, 1966.

Among 9 patients whose gastric pH levels fluctuated by more than 1 full value (e.g., 0.8-2.2) in measurements made every 5 min. over a period of 1 hr., i.v. inj. of 25 mg Opipramol (Insidon) virtually eliminated the fluctuations in question. Among 17 patients (6 men, 11 women) with gastric hyperacidity, peroral admin. of the same drug for 5-22 days significantly reduced the increase in gastric acidity which followed peroral admin. of caffeine sodium benzoate. There also appeared to be a tendency to shorten the duration of such increase.

- 10124 INTESTINAL HETEROTOPIA. A FINE STRUCTURAL STUDY. (E.) Rubin, W. (Cornell U. Coll. Med., New York, N. Y.), L. L. Ross, G. H. Jeffries and M. H. Sleisenger. Lab. Invest. 15(6):1024-1049, 1966.

Aberrant intestinal epithelium which occurs in the atrophic stomachs of patients with pernicious anemia was found to be similar in histologic organization and in fine structure to that of normal human jejunal epithelium. These epithelial cells of intestinal type appeared to be isolated from those of gastric type; no common precursor cell could be identified. These factors contribute to the thesis that this tissue represents a "heterotopia" rather than a "metaplasia." The concept of an intracellular skeleton is further developed by the observations of lateral cytoplasmic bundles of filaments, associating the microvilli through their filaments with the lateral cell membranes, the desmosomes, and thereby, adjacent cells. These abnormal stomachs with mixed epithelial cell populations provide an interesting model for the study of the origin, differentiation and proliferation of gastrointestinal epithelial cells.

- 10125 SELECTIVE GASTRIC VAGOTOMY VERSUS TOTAL ABDOMINAL VAGOTOMY. (E.) Hedenstedt, S. (Dept. Surgery, Lasarettet, Nacka, Sweden) and G. Lundquist. Acta Chir. Scand. 131(6):448-459, 1966.

Forty-four patients who had undergone bilateral selective vagotomy, 6 who had undergone anterior selective and posterior total vagotomy and 30 who had total abdominal vagotomy were studied for 6 mo.-2.5 yr. Completeness of the vagotomy was assessed by the gastric secretory response to insulin (Hollander's method) and histamine. Vagotomy was found to be complete in all anterior selective and posterior total patients, in 42 of 44 patients undergoing the bilateral selective procedure and in 27 of 30 total vagotomies. Four of 50 patients undergoing selective vagotomy had mild diarrhea, 15 of 30 total vagotomy patients had diarrhea, mild in 6 cases and moderate to severe in 9 cases. The frequency of dumping was 14% after selective vagotomy compared to 23% after total vagotomy.

- 10126 VALUE OF β -GLUCURONIDASE ACTIVITY IN GASTRIC JUICE IN THE DIAGNOSIS OF GASTRIC CARCINOMA. (E.) Piper, D. W. (U. Sydney, Australia), E. M. Griffith, L. G. Irving and B. H. Fenton. Gastroenterology 51(2):172-179, 1966.

histamine-stimulated (0.02 mg/kg s.c. + 100 mg mepyramine) gastric secretions were collected from fasting patients, 33 with gastric carcinoma, 50 with gastric ulcer and 9 controls, both simply and following atropine i.v. (0.63 mg) and gastric lavage with 3.75% sodium bicarbonate soln. The actual 10-min. samples used for enzyme studies were collected following intragastric inj. of 20 ml of this soln. The enzymatic activity of the collected juice was determined by Plaice's method, and by Ceriotti's method. Enzyme activity was expressed in terms of protein conc. in the neutralized gastric juice. β -Glucuronidase activity of less than 1.35 U/mg soluble protein (normal limits) was found in 47 of 50 gastric ulcer patients. Twenty-five of the 33 gastric carcinoma patients had values above 1.35 U. It was concluded that increased β -glucuronidase activity was usually indicative of cancer. There was a significant negative correlation between acid output and enzyme activity in the carcinoma group only. β -Glucuronidase activity is partially acid-dependent, activity being favored by carcinoma and a low acid secretory ratio. Gastric β -glucuronidase activity is irreversibly inactivated at pH levels lower than 3.8, optimal activity occurring at pH 4.5. Determination of β -glucuronidase activity is suggested as useful for diagnostic purposes to indicate malignancy in patients with radiologic indications of ulcerative or space-occupying gastric lesions.

0127 MEASUREMENT OF GASTRIC EMPYTING-RATE. (E.) Brömster, D. (Serafimer Hosp., Stockholm, Sweden), G. Carlberger and G. Lundh. Lancet 1(7456): 224-225, 1966.

In this method the thyroid gland is blocked before examination and an oral dose of radioactive iodinated human serum albumin which is rapidly digested and absorbed in the duodenum and upper part of the jejunum, and thus will not interfere with external counts. The main problem has been the resecretion of liberated iodine by the gastrointestinal iodine pump. Seventy subjects were studied. Duodenal ulcer patients began to empty faster than healthy individuals; whereas, gastric ulcer or cancer patients showed a delay in emptying with the same test meal volume. Healthy individuals showed a delay in emptying with increase in test-meal volume.

0128 GASTRIC ACID SECRETION IN CHRONIC IRON-DEFICIENCY ANAEMIA. (E.) Jacobs, A. (Welsh Nat. Sch. Med., Cardiff, Wales), J. H. Lawrie, C. C. Entwistle and H. Campbell. Lancet 2(7456):190-192, 1966.

Gastric acid secretion was measured by the histamine infusion technic in 44 patients with chronic iron-deficiency anemia. Thirteen had a complete histamine-fast achlorhydria and an additional 22 had a max. acid output below normal. No patient over 50 yr. of age had a normal acid output. After treatment of the anemia all patients below the age of 30, except one, had an acid secretion in the normal range. In patients over 30 yr. of age impaired gastric function does not usually improve with treatment of the anemia and may even progress further. The parietal cell antibody may simply be a result of gastric mucosal damage and not a cause of the irreversible atrophic process. No evidence was found that primary gastric atrophy is a common cause of iron-deficiency anemia, which may result in an irreversible impairment of gastric function.

0129 PSEUDOTUMORS OF THE STOMACH. (E.) Sanowski, R. A. (New Jersey Coll. Med. and Dent., Jersey City) and J. DiBianco. Am. J. Dig. Dis. 11(8): 607-614, 1966.

The case of trichobezoar, 2 cases of phytobezoar, and 2 cases of food boli, in which cinefibergastroscopy aided in diagnosis, are presented. In the case of trichobezoar, X-rays demonstrated an intraluminal filling defect while fibergastroscopy revealed a large black mass with strands of hair. The patient made an uneventful recovery following surgical removal and later, admitted eating her hair for several years. The two cases of phytobezoar were due to the lodging of prune pits in the gastric antrum. Early studies in each case revealed an ulcer, while fibergastroscopy detected the prune pits, which were confused with polyps on the X-rays in one case. Both patients refused removal of the pits. Both cases of food boli were subjected to fibergastroscopy because the symptoms indicated the

STOMACH

possibility of gastric malignancy. In each case the finding was a large fungating mass on the greater curvature aspect of the antrum with no surrounding inflammation as is usually seen with carcinoma. In one case a biopsy was performed and proved to be vegetable fibers. Both cases cleared up after gastric lavage. With the use of both X-rays and endoscopy films, the correct diagnosis can be established.

- 10130 LONG-TERM OBSERVATION OF GASTRECTOMIZED RATS WITH REGARD TO DEVELOPMENT OF VITAMIN B₁₂ DEFICIENCY. (E.) Nygaard, K. (U. Hosp., Oslo, Norway), A. Killander, E. Myhre and N. Helsing. Scand. J. Haemat. 3(3):213-221, 1966.

Gastrectomized rats (glandular part of stomach excised) kept in good nutritional condition by feeding with added ferrous gluconate (0.2 g/day) survived 16-26 mo. postoperatively. B₁₂ absorption was studied by dosing p.o. with Co⁵⁸-labeled B₁₂ and collecting and counting the feces over a 4-day period. B₁₂ activity in serum and liver and folic acid in liver was determined for 7 rats 17-22 mo. postoperative by microbiological methods. The forestomach in all surviving rats had retained its original size and was normal histologically. Liver and spleen were found to be normal upon microscopic examination. Rats receiving supplemental iron maintained normal hemoglobin levels. B₁₂ was poorly absorbed in operated rats, 83.3% excretion of ingested dose compared to 34.4% in normals. Mean B₁₂ serum conc. in gastrectomized rats was 16% of normal, liver conc. 28% of normal. Folic acid levels were approx. normal. Although the rats showed defective iron absorption, megaloblastic anemia did not develop. The following were suggested as possible explanations for these findings: B₁₂ depots may be large in the rat, absorptive capacity may be large, the rat may save B₁₂. The normal levels of folic acid suggested that perhaps folic acid is a B₁₂ substitute in the rat.

- 10131 EFFECT OF TRUNCAL AND SELECTIVE VAGOTOMY ON DUODENAL ASPIRATES IN MAN. AMYLASE, PROTEASE AND LIPASE RESPONSE TO SECRETIN AND PANCREOZYMIN STIMULATION. (E.) White, T. T. (U. Washington, Seattle), S. G. Lenning, R. G. Elmslie and D. F. Magee. Ann. Surg. 164(2):257-266, 1966.

Subjects were intubated with a Matzner duodenal tube modified to include a second catheter for the inj. of dye. The end of the tube was placed (by X-ray guidance) close to the Ampulla of Vater and 28.3 ml/hr. of phenosulfophthalein (50 mg/liter of 0.9 N saline) was infused. Duodenal contents (15-min. samples) were collected before and after i.v. inj. of secretin and Cecekin (One U of Cecekin contains 1 U cholecystokinin and 4 U pancreozymin). Normals (29), Billroth I patients (26) Billroth I patients (15) with selective vagotomy, Billroth I patients (21) with truncal vagotomy and pyloroplasty patients (12) were studied with single doses of 1 U secretin and 1 U secretin combined with 1 U Cecekin. Fifteen Billroth I patients, 7 with truncal vagotomy, were studied with continuous inj. of secretin (0.25 U/min./hr.) and secretin (0.25 U/min./hr.) plus Cecekin (0.25 U/min./hr.). Amylase, protease, and lipase were determined. Relative dilution and fluid loss were determined from dye conc. Secretin and secretin-Cecekin response-curves in patients with partial gastrectomy with truncal or selective vagotomy were similar, nor was there a difference between truncal and selective vagotomy patients with pyloroplasty.

- 10132 GLUCOSE TOLERANCE CURVES AFTER PARTIAL GASTRECTOMY. RELATIONSHIP TO POSTGASTRECTOMY SYMPTOMS. (E.) Amdrup, E. (Commun. Hosp., Copenhagen, Denmark), B. Kortholm and S. P. Nielsen. Acta Chir. Scand. 131(5):461-472, 1966.

To study the "hypoglycemic syndrome" reported to occur after gastrectomy, 102 glucose tolerance tests (p.o. 1 g glucose/kg in 10% soln., blood sugar determined for 3 hr.) were done in 88 Billroth II patients and 4 who had undergone Zacho's segmental resection. The effects of 50% glucose and posture during testing were also studied. The patients were identifiable symptomatically as: a) Dumping, b) small stomach, c) uncharacteristic. Higher max. were seen in the glucose tolerance curves of postgastrectomy patients than normals. Dumping patients had a high value which was reached in the same time a lower value was reached in the other patients; similar results were obtained using a 50% glucose soln. Contrary to

TOMACH

Normals gastrectomy patients showed a flat tolerance curve in the horizontal position. Similar curves were seen with the segmental repair patients with gastric retention. In both groups the peak was reached late. Some of the symptoms and abnormalities of the glucose tolerance curves of postgastrectomy patients could be explained by changes in rate of gastric evacuation.

- 0133 EFFECT OF ASPIRIN ON EXPLANTED GASTRIC MUCOSA. (E.) Stephens, F. O. (U. Sydney, Australia), G. W. Milton and J. Loewenthal. Gut 7(3):223-227, 1966.

In 16 dogs a section of full thickness gastric wall with intact blood supply was brought through an incision in the abdominal wall and sutured over a comparable area from which the skin had been removed. Immediately after the explant was completed the dogs were given histamine (0.5 mg/kg i.m.); the pH of the explant was determined with universal indicator paper. In 8 dogs half the explanted mucosa was covered with 0.5 g powdered aspirin. After 1 hr. the aspirin was removed and histamine response was redetermined. The histamine test was repeated 24 hr. later. In 2 experiments after aspirin, histamine was repeated every 2 hr. for 24 hr., the dogs remaining anesthetized. Biopsy specimens from the explants were taken at all stages of all experiments. The surface of the fresh explants had a pH of 9-10; after histamine, pH was 1-2. Control dogs showed acid response to histamine for a minimum of 3 days. Aspirin blocked further secretion; the adjacent part secreted acid immediately but had ceased 24 hr. later. The repeated inj. of histamine failed to stimulate the covered area; the uncovered area secreted after 24 hr. Aspirin produced edema and hemorrhagic petechiae which grew more severe over 48 hr. Histologically, there was a little intercellular edema immediately after aspirin removal; 24 hr. later subepithelial red cells and inflammatory cells appeared along with progressive loss of epithelial cells and an increase of edematous spaces and eventually a complete loss of surface epithelium. The deeper structures were unaffected until 48 hr. had passed. No evidence of absorption of aspirin was seen. The uncovered area showed similar but less severe changes; histamine repeated every 2 hr. blocked these changes in the uncovered mucosa. It is concluded on the basis of the protection offered by repeated inj. of histamine that acute aspirin gastritis is not the result of increased acid secretion.

- 0134 GASTROSCOPY. ITS VALUE IN THE DIAGNOSIS OF ULCER OR TUMOR OF THE STOMACH. (E.) Øyen, O. (Aker Hosp., Oslo, Norway). Acta Chir. Scand. 131(5):454-460, 1966.

A series of 419 patients with suspected ulcer, tumor or gastric bleeding were examined by gastroscopy (Wolf-Schindler gastroscope). Gastroscopic findings were compared to results of reexamination and findings at surgery or autopsy. In 174 cases reexamination and gastroscopy agreed and demonstrated abnormal findings. In 15 instances the gastroscopic examination failed compared to reexamination and in 22 cases gastroscopic examination was superior to reexamination. Gastroscopy was unsuccessful in 22 cases due to organic obstruction or lack of surgeon-patient cooperation. The esophagus was perforated in one patient who died. It is concluded that gastroscopy cannot replace reexamination but is a helpful complement, and can be decisive, particularly in discriminating between an ulcer and carcinoma, or in cases involving bleeding.

- 0135 CHRONIC GASTRITIS AND GASTRIC ULCER. (E.) Mackay, I. R. (Eliza Hall Inst. Med. Res., Melbourne, Australia) and I. G. Hislop. Gut 7(3):228-233, 1966.

Brief case histories were given for 9 patients in whom gastric ulceration and/or bleeding occurred as a complication of chronic gastritis; 6 patients had undergone partial gastrectomy. Gastric acid production was studied following 0.3 or 0.6 mg of histamine. Serologic analyses were done including testing for complement-fixing autoantibodies to stomach antigen. Gastric biopsy was done by suction tube. Material aspirated during biopsy was cultured both aerobically and anaerobically. All patients showed impaired acid production following histamine. Biopsy material showed glandular atrophy, disorganization and infiltration of the lamina propria with lymphocytes and plasma cells; lymphoid follicles were seen frequently. The

STOMACH

gastritis was not zonal in character. The histologic appearance of the stomach tissues was indicative of an immunologic response in the wall of the stomach; in 5 cases this finding may have been related to bacterial infection (3 cases) or autoimmunity. Etiology was unclear in the other 4 cases. It is suggested that chronic atrophic gastritis may be an important determinant of gastric ulceration and bleeding.

- 10136 INTRAGASTRIC PRESSURE MONITORING. AN ADJUNCT TO GASTRIC HYPOTHERMIA. (E.) Moss, G. (Albany Med. Coll., New York). Arch. Surg. (Chicago) 93(2):291-294, 1966.

Mongrel dogs were used to test a modified technic for producing gastric hypothermia in which the intergastric pressure is continuously monitored to reduce the danger of rupture of the gastric wall. An ordinary thin latex sheath was attached to a tube having 3 lumens, 1 each for delivery and return of coolant and 1 for pressure recording; this lumen was coupled to a strain gauge and a multichannel recorder, which also recorded the electrocardiogram and the rectal temperature. Cooling was accomplished by commercial hypothermia units. In 1 group of 3 dogs, after condom and tube were passed orally into the stomach and the initial introduction of 250 ml of 30% ethanol to establish a baseline pressure, a pump circulated the coolant until the intragastric pressure rose to 10 mm Hg, while the stomach was being observed through a ventral midline incision in the anesthetized animal. Monitoring continued until the rectal temperature fell 7° C with a coolant temperature of 9° C. In a second group of 8 dogs under anesthesia but not operated upon, the same general technic was employed but with 2 differences. The vol. of coolant employed in the system was increased until the intragastric pressure initially measured 10 mm Hg. This pressure was not exceeded during the cooling process. With the use of an Armstrong unit, tap water was substituted for ethanol. Cooling was adequate. Test admin. of 1000 ml of fluid into the empty human stomach showed this vol. is well tolerated with a pressure rise of only 2-4 mm Hg. In some patients fitted with balloon and triple-lumen tube for hypothermia, the introduction of only 500 ml or less raised the intragastric pressure to 10 mm Hg because of the presense of intragastric blood clot due to esophageal or gastric bleeding which hypothermia is designed to control. In addition to gastric rupture which is almost universally fatal, another danger lies in the use of potentially lethal vol. of ethanol soln. This hazard was eliminated by using the Armstrong unit which circulated tap water. Pressure values, however small in excess of 10 mm Hg, are indicative of overdistention of the stomach.

- 10137 A COMPARATIVE MORPHOLOGICAL AND FUNCTIONAL STUDY OF GASTRITIS WITH AND WITHOUT AUTOANTIBODIES. (E.) Te Velde, K. (U. Groningen, The Netherlands). P. J. Hoedemaeker, G. J. P. A. Anders, A. Arends and H. O. Nieweg. Gastroenterology 51(2):138-148, 1966.

Chronic gastritis was studied in 131 patients: 29 with pernicious anemia (17 with parietal cell antibodies in their serum and 12 without), 69 with parietal cell antibodies of which 59 were without acid in their gastric juice following histamine s.c. and 33 achlorhydric subjects without serum antibodies. Gastric juice was obtained by aspiration for 2 hr. following s.c. histamine (0.5 mg). Four types of gastritis were distinguished: superficial (SG), mucosa normal width, parietal and chief cells normal; chronic multifocal gastritis (CMG), patches of normal mucosa, and areas with no normal glandular elements; diffuse atrophic gastritis (DAG), specific elements reduced or absent, decreased mucosal width; gastric atrophy (GA), severe atrophy, no parietal or chief cells. In pernicious anemia patients and in achlorhydric patients with antibodies, DAG and GA were most often observed. Schilling tests indicated subnormal absorption of B₁₂ in 31 of 50 achlorhydric patients. In similar patients without antibodies, CMG was most often observed, subnormal Schilling tests were found in 3 of 26. In parietal cell antibody-positive patients that produced gastric acid, B₁₂ absorption was normal and less damage to fundus glands was observed. DAG was most frequently seen in parietal cell antibody positive patients; patients lacking these antibodies most often showed GA. Intrinsic factor antibodies were found in only 3 subjects with a normal Schilling test. Intrinsic factor antibodies appeared correlated with severity of gastritis. It is

TOMACH

concluded that chronic gastritis in parietal cell positive patients may terminate in pernicious anemia. Chronic gastritis without parietal cell antibodies is functionally and morphologically different from gastritis when antibodies are present. Antibodies to intrinsic factor may be found in achlorhydric subjects with parietal cell antibodies, but are more often found in pernicious anemia. Therefore it is recommended that such patients with parietal cell antibodies should be investigated for the presence of intrinsic factor in their gastric juice; if such were lacking they could be protected by the prophylactic admin. of B₁₂.

- 0138 ANGIOGRAPHY IN TUMORS OF THE STOMACH. (E.) Boijesen, E. (U. Lund Hosp., Sweden), S. Wallace and I. E. Kanter. Acta Radiol. [Diagn.] (Stockholm) 4(3):306-320, 1966.

Patients with benign (2 of 31) and malignant (29 of 31) gastric neoplasms were examined by selective celiac angiography (Seldinger technic, via the femoral or axillary artery), supplemented in 6 patients with selective superior mesenteric artery angiography to determine the value of the method in the differential diagnosis of tumors. Benign and malignant conditions could not be differentiated, both types showing hypervascularity, luminal irregularities, and accumulation of contrast medium. Extension of the primary tumor to the liver, hepatoduodenal ligament, duodenum, and the splenic hilum was readily demonstrated in 11 patients, but extensions to the omentum, pancreas, diaphragm, retroperitoneal area, and the abdominal wall were poorly outlined. Differentiation of extrinsic from intrinsic gastric lesions was made by delineating the origin of the tumor's vascular supply. The measured diameters of the primary arteries all fell within the range of normal.

- 0139 VASCULAR HYPERTONICITY. A MECHANISM FOR VASODILATATION IN THE DUMPING SYNDROME. (E.) Lucas, C. E. (Wayne State U. Sch. Med., Detroit, Mich.) and R. C. Read. Surgery 60(2):395-401, 1966.

One group of prepared dogs had a 1-inch tube introduced orally and manipulated into the duodenum below the pancreatic duct for the introduction of 150-200 ml of 50% glucose in water or 10% NaCl. Isotonic fluids or intragastric inj. with or without pyloric ligature served as controls. The role of vascular hyperosmolality was studied in a large number of dogs in which these parameters were measured: systemic arterial pressure, portal and arterial hematocrits, osmolality, serum sodium and glucose. In a second group of 32 dogs, the thoracic duct was cannulated. Arterial blood and thoracic lymph were collected prior to and at 15-min. intervals following production of dumping and bioassayed on ox carotid strip and guinea pig ileum for vasoactivity. Cross circulation in another group of 16 dogs with recipient isolated kidneys for vascular response was used to study dumping employing the same parameters as before. In a group of 12 paired dogs the same experiment was repeated with hypertonic glucose or saline admin. i.v. instead of intraduodenally. In other studies, the dumping syndrome was produced in 18 patients with and without ulcer diathesis by intraduodenal introduction of 150-200 ml of 50% glucose. Blood pressure was recorded and venous blood analyzed for hematocrit, glucose and osmolality. A second group of 16 human unoperated subjects received 150 ml of 50% glucose or 10% saline by rapid i.v. inj. The bioassay experiments demonstrated no consistent change in vascular reactivity. However, all the technics demonstrated that increased osmolality of blood, whether derived from glucose or from NaCl by enteral or by parenteral route, caused decreased resistance in the vascular bed with a high degree of correlation.

- 0140 SOME ALTERED GASTRIC MUCINS ASSOCIATED WITH ESOPHAGOGASTRIC ULCERS IN SWINE. (E.) Curtin, T. M. (Purdue U., Lafayette, Ind.) and G. D. Goetsch. Am. J. Vet. Res. 27(119):1013-1016, 1966.

Based on the results of examination of gastric lesions at necropsy paraffin-embedded esophagogastric tissues from more than 800 pigs were grouped into 5 classes (in terms of increasing severity and time course): normal, abnormal cornification, eroded, ulcerated, and healed after ulceration. Five tissues selected at random from each group were sectioned and stained by a periodic acid-Schiff colloidal iron method. This procedure discriminates between mucosubstances containing vicinal hydroxyl groups (magenta) and those with free carboxyl groups (Prussian blue). The

STOMACH

glandular mucosa adjacent to the squamous areas of the stomach was examined and the staining character of 1,000 cells recorded for each slide. As lesions became more advanced there was a decrease in the number of cells with vicinal hydroxyl groups. Healed stomachs had approx. the same number of these groups as normals. There was an increase in the number of cells containing carboxyl groups as the lesion developed; there was no similarity however, between normal and healed tissues. There was no correlation between the number of cells containing both groups and the severity of lesions. It was concluded that these data offer support to the proposed pathogenesis of these lesions which is believed to be an initial excessive cornification followed by surface erosion and ulceration. The progressive alterations in the chemical nature of the gastric mucins paralleled this sequence of tissue changes.

- 10141 ALKALINE AREAS IN GASTRIC MUCOSA AFTER GASTRIC SURGERY. (E.) Capper, W. M. (Southmead Hosp., Bristol, England), T. J. Butler and K. G. Buckler Gut 7(3):220-221, 1966.

Reoperation following previous gastric operation permitted the pH of gastric mucosa to be directly determined during continuous histamine stimulation. Nine patients all required additional surgery due to recurrence of ulcers, steatorrhea or other difficulties. Two had undergone the Billroth I operation, 4 Polya operations, 2 had gastrojejunostomy and 1 had hemigastrectomy with Roux-en-Y anastomosis. In each case the gastric remnant was opened and pH recorded from the anastomosis towards the fundus. Despite previous excision of the alkaline zone (antrum) there was a new alkaline zone in each case adjacent to the soma. This was not the case with the Roux-en-Y anastomosis, the only exception. The appearance of a new alkaline zone in an area previously acid-secreting was assumed to indicate the disappearance of oxyntic cells due to duodenal reflux. These findings were considered confirmatory of those earlier collected in dogs by Lawson (1964).

- 10142 THE GASTRIC MUCOSA IN ANAEMIA IN PUNJABIS. I. IN IRON-DEFICIENCY ANAEMIA. (E.) Cowan, B. (Brown Mem. Hosp., Ludhiana, Punjab, India), S. Joseph and V. K. Satija. Gut 7(3):234-238, 1966.

Gastric mucosal biopsies were obtained in 70 patients suffering from iron-deficiency anemia, 33 had hookworm infestation, 14 had a history of bleeding (menorrhagia or hemorrhoids). The mucosal specimens were evaluated by 2 pathologists independently under blind conditions. Gastric acidity was determined following admin. of histamine (0.04 mg/kg). Gastric mucosal abnormalities were found in 43 patients; 29 were diagnosed as superficial gastritis and 14 as atrophic gastritis. Gastric atrophy without cellular infiltration was not found. Of patients with atrophic gastritis only 2 had hookworm infestation; the incidence of hookworm infestation in superficial gastritis was approx. the same. Of patients without hookworm infestation 14 had a history of bleeding. Of 47 cases with bleeding or hookworm only 5 had atrophic gastritis; of 23 patients without bleeding or hookworm 9 had atrophic gastritis. Eleven atrophic gastritis cases had complete achlorhydria; the relationship between acid output and histology of the gastric mucosa was similar to that reported earlier, i.e. the more severe the gastritis the less acid. Acid output in hookworm patients and in the hemorrhagic group was higher than in the "idiopathic" group. Since the ages of the patients in the 2 groups, hemoglobin levels, serum iron levels and incidence of koilonychia and glossitis were similar it was suggested that nutritional deficiency due to diet or small intestine disease is a more important factor than iron deficiency in the pathogenesis of chronic atrophic gastritis.

- 10143 THE GASTRIC MUCOSA IN ANAEMIA IN PUNJABIS. II. IN MEGALOBlastic ANAEMIA. (E.) Cowan, B. (Brown Mem. Hosp., Ludhiana, Punjab, India), S. Joseph and V. K. Satija. Gut 7(3):238-243, 1966.

Gastric mucosal biopsies were obtained from 17 male and 13 female patients with megaloblastic anemia. Abnormal gastric mucosa was found in 23 of 30 patients, superficial gastritis in 9 and atrophic gastritis in 14. All of the latter cases were accompanied by marked cellular infiltration. The relationship between severity of gastritis and gastric acidity was similar to that previously reported; 7 of 14 cases of atrophic gastritis were achlorhydric following stimulation with

TOMACH

histamine (0.04 mg/kg), and in 5 others max. acid output ranged from 1.2-2.1 mEq. achlorhydria was not found in any of the 16 patients with normal mucosa or superficial gastritis. The hemoglobin levels av. 6.2 g%; there was no correlation between degree of anemia and incidence of atrophic gastritis. Of 17 patients with a history of diarrhea 6 had atrophic gastritis. The incidence of steatorrhea was approx. equal for patients with and without atrophic gastritis. Generally the diet of the whole group was poor. Of 10 patients eating mostly grain and vegetables 6 (3 eating only maize) had atrophic gastritis suggesting that the incidence of the gastric mucosal lesion might be greater in severe dietary deficiency. There was a tendency for atrophic gastritis to occur more frequently in patients showing the pigmented skin lesions typical of pellagra or in patients who, in fact, had pellagra. Thirteen patients responded to folic acid, 4 to B₁₂ and 10 to folic acid and B₁₂. It was not possible to draw conclusions from the response to therapy and the incidence of atrophic gastritis. It is suggested that nutritional deficiency may be of importance in chronic atrophic gastritis.

0144 TUBELESS GASTRIC ANALYSIS TECHNIQUES IN DIAGNOSIS OF CHRONIC GASTRITIS.
(E.) Segal, H. L. (U. Rochester Sch. Med., N. Y.) and I. M. Samloff.
J.A.M.A. 197(9):717-718, 1966.

The histologic appearance of peroral gastric mucosal biopsy specimens was correlated with the estimation of acid secretion with azuresin (tubeless gastric analysis) and measurement of uropepsin activity. All subjects with normal mucosa (13) secreted acid and uropepsin activity ranged between 25 and 162 U/hr. Seventeen of 24 with superficial gastritis did not secrete acid and uropepsin activity ranged between 0-727 U/hr. The uropepsin activity in the acid-secreting superficial gastritis patients ranged between 88 and 580 U/hr. Only 1 of 22 of the atrophic gastritis patients had gastric acid and normal uropepsin activity; in this group uropepsin activity ranged from 0-32 U/hr. Three patients showing complete gastric atrophy secreted no acid and excreted no uropepsin. The combined findings of no acid and low uropepsin activity were taken as indicators of atrophic gastritis or complete mucosal atrophy. The diagnosis of gastritis by use of azuresin is concluded to be of clinical significance in 1) management of a patient with a gastric ulcer niche, 2) selecting patients for further study for detection of carcinoma or B₁₂ deficiency, 3) suggesting the diagnosis of chronic gastritis as a possible cause of upper gastrointestinal bleeding in an individual with negative X-ray findings. Absence of acid and low uropepsin activity in a patient with a gastric ulcer niche was suggested as an indication for surgery. The possibility of B₁₂ deficiency should always be considered in the elderly patient with atrophic gastritis or atrophy. It is concluded that the technic provided a simple and practical approach to the diagnosis of chronic gastritis.

0145 ASPECIFIC REACTIVE GASTRITIS. (It.) Camarri, E. (U. Siena, Italy), G. Bassi, R. Lunghetti and M. Montagnani. *Minerva Med.* 57(17):697-701, 1966.

The term "aspecific reactive gastritis" is applied to gastritis associated with other diseases, presenting a variable clinical and functional picture, and having a characteristic histologic finding of sharply circumscribed periglandular small cell and granulocytic inflammatory infiltrate in the subepithelial tissues with little or no alteration in the rest of the gastric mucosal structures. The diagnosis was made from gastric aspiration biopsies in 100 patients (15-79 yr.), 46 of whom had primary gastrointestinal diseases, 21 diseases of the hepatobiliary system, and 33 other diseases. The most common symptoms were epigastric pain and heaviness. Gastric secretion was normal in 34 patients, elevated in 53, and below normal in 13; 5% of the patients had hypo- or achlorhydria. Of the 92 patients who had radiologic examination of the stomach, 41.3% had normal films, 27.1% showed hypotonicity, 7.6% hypertonicity, and 14.1% had signs of gastritis. Only 2 of 20 patients who had second biopsies, 3-21 mo. after the first, showed the findings of aspecific reactive gastritis; 12 (60%) had normal biopsies, and 6 (30%) had developed superficial or atrophic chronic gastritis.

STOMACH

- 10146 GASTRITIS AND GASTRIC ULCERATION. (E.) Lawson, H. H. (U. Witwatersrand, Johannesburg Gen. Hosp., South Africa). Brit. J. Surg. 53(6):493-496, 1966.
- Experiments with dogs using explants of antral and fundic mucosa indicate that atrophic gastric mucosa will regenerate once the cause of the gastritis is removed provided that the affected area is not in contact with the gastric secretion. When an area of atrophic gastritis was exposed to the action of gastric content, initial gastric ulceration occurred. During the progressive (40-120 days) atrophic gastritis of these explants, many parietal cells were extruded into the lumen between days 2 and 6 of exteriorization. When these explants were reimplanted within the stomach by being placed on the serosal surface of the stomach, regeneration was completed in about 6 days. Antral mucosa and fundic mucosa of the normal stomach were equally capable of protecting the explant to some degree, but not sufficiently to prevent initial ulceration. Yet regeneration of fundic mucosa took longer than regeneration of antral mucosa. The antrofundic junction did not represent an area of increased susceptibility to ulceration in the 3 dogs where the explant was included in this area.

SMALL INTESTINE

222 INVERTING OR EVERTING SUTURES FOR BOWEL ANASTOMOSES. AN EXPERIMENTAL STUDY. (E.) Mellish, R. W. P. (U. Vermont Coll. Med., Burlington). J. Pediat. Surg. 1(3):260-265, 1966.

Crane-Dawley rats (200-500 g) were used to test the relative values of inverting and everting intestinal anastomoses with regard to strength, healing, and formation of adhesions. The operations were carried out under sterile surgical conditions. After laparotomy the ileum was divided 10 cm from the ileocecal valve. The method of anastomosis was alternated to obtain equal numbers of inverting and everting anastomoses. Each inverting type was carried out end-to-end with a single row of interrupted Lembert sutures of 7.0 atraumatic silk; the needle was carried through the full thickness of the wall to include the mucosa. Each everting anastomosis joined the full thickness of the wall with a single row of simple interrupted 7.0 silk sutures apposing mucosa to mucosa. The abdominal wound was closed with continuous atraumatic 5.0 chromic catgut for the fascia and skin in two layers. The strength of the operations was tested by hydrostatic pressure. The suture line was weak from 24 hr. until the end of day 3, increasing thereafter in strength to the max. test pressure (200 mm Hg). The 2 groups did not differ in healing strength according to this test. The data from the study of adhesions were tried by a modified Wilcoxon test. The data strongly suggest that the everting procedure increased the chance of formation of adhesions.

223 CHANGES IN THE VILLOUS PATTERN OF THE HUMAN JEJUNUM ASSOCIATED WITH HEAVY RADIATION DAMAGE. (E.) Wiernik, G. (St. Thomas' Hosp., London). Gut 7(2):149-153, 1966.

Jejunal biopsy specimens were obtained from 6 patients who had undergone partial total gastrectomy for carcinoma of the stomach and had undergone postoperative radiation (cobalt teletherapy unit). This paper reports only on changes in mucosal pattern. Pre-irradiation biopsies showed a normal pattern. Following radiation mitotic activity in the crypts diminished and the number of epithelial cells lining the crypts and the villi decreased. By day 11 the mucosa appeared flat, the villous structure was lost and the crypts unrecognizable. After recovery from radiation damage (day 53) the villous pattern was one of convoluted and folded villous ridges--the villous structures spanned several crypts, the crypts themselves were of normal appearance. It is suggested that these rapid changes in the mucosal pattern are directly linked with alterations in the epithelial cell system that forms the lining of the villus and the crypt.

224 ACUTE SIMPLE OBSTRUCTION IN THE RAT. (E.) Kraft, B., H. Sutton, P. C. Brennan and R. J. M. Fry. Argonne Nat. Lab. Ann. Rep. (ANL-7136) 1965: 71-72, 1966.

Initial investigations into the effect of diverting bile and of antibiotic treatment on survival time following acute simple obstruction in 35 young adult male rats are presented. The length of obstructed intestine was standardized and in neomycin-treated groups the antibiotic was given in drinking water (2 mg/ml) for 3 days prior to operation and postoperatively. The mean survival is presented for each type of obstructive treatment with the highest being 102.5 hr. with high obstruction with common bile duct tied and neomycin. Diversion of bile to a point distal to the obstruction or preventing bile from reaching the intestinal lumen increased survival time. Inj. ^{131} I-albumin was measured 2 hr. after inj. in the intestine obstructed for 15 hr. No difference was evident between the intestine with simple obstruction and that with simple obstruction plus the common bile duct tied. The presence of bile within that period did not increase permeability of mucosa for albumin. Bile contributes to loss of fluid and electrolytes on the basis of the evidence obtained. The short length of obstructed gut is unable to absorb secretions and water drunk postoperatively. The obstructed intestinal segment provides a test system for study of interaction of bile and bacteria, but further antibiotics must be investigated.

SMALL INTESTINE

- 10225 THE IRON CONTENT OF JEJUNAL MUCOSA OBTAINED BY CROSBY'S BIOPSY IN HEMOCHROMATOSIS AND HEMOSIDEROSIS. (E.) Astaldi, G. (Municipal Hosp., Tortona, Italy), G. Meardi and T. Lisino. Blood 28(1):70-82, 1966.

Twenty healthy volunteers, 10 patients with acquired hemosiderosis and 1 congenital hemochromatosis patient underwent peroral biopsy of the small intestine (Crosby instrument) after 18 hr. fasting, at distances of 75-140 cm from the incisors. The tissues were fixed, sectioned and subjected to testing for hemosiderin (Perl's test). Areas of 250 villi were examined and the following determined: 1) % of Perl's positive villi; 2) number positive granules in the pericryptic tunica propria and submucosa; 3) degree of Perl's-positivity rated as 0, 1, 2, or 3; 4) av. degree positivity. In healthy subjects hemosiderin was absent from the duodenum; in the jejunum hemosiderin was absent in the columnar epithelium, but present in the tunica propria of several villi. The positive villi increased with distance from incisors. The granules were contained within the cytoplasm of macrophages at the tips of the villi. There was no hemosiderin found in the columnar epithelium of hemosiderosis patients. In the duodenum and jejunum 30-60% of the villi showed siderotic macrophages in their stroma, containing large granules or masses of hemosiderin. These were located at the tips of the villi and in some cases appeared to be traversing the columnar epithelium or outside it. The degree of positivity increased with distance from the incisors. In hemochromatosis the columnar epithelium contained granules increasing with distance from the incisors until 10% of the villi were affected. The villi (40-75%) showed macrophages containing iron in the tunica propria. The macrophages were not only in the tips of the villi but distributed in the tunica propria or around the vessels; none seemed to be traversing the columnar epithelium or outside it.

- 10226 DYNAMIC ASPECTS OF SMALL INTESTINAL RUPTURE WITH SPECIAL CONSIDERATION OF ANASTOMOTIC STRENGTH. (E.) Nelsen, T. S. (Stanford U. Sch. Med., Palo Alto, Cal.) and C. J. Anders. Arch. Surg. (Chicago) 93(2):309-314, 1966.

Segments of healthy mongrel dogs ileum (10 cm or more in length) were excised with the previous anastomosis near the middle of the piece. The cut ends of the ileum in the dog were carefully sutured. All segments were adjusted to a 6-cm collapsed length by attachment of the ends to grooved rubber stoppers with securely tied cotton tapes. The stoppered length of ileum was filled with water with the removal of contained air. Water flow to produce pressure rises within the section were at 2 ml/min., 12 ml/min., and 50 ml/second. Pressure in the hydraulic system was continuously recorded by means of a potentiometric transducer connected to a curvilinear electric penwriter. Measurement of external diameter of intestinal section was by caliper. Diameter was measured at the beginning of test and at the time of leakage or bursting. Changes in diameter with the most rapid inflow (50 ml/second) was recorded through the use of rapid (1000 frames/second) motion pictures against a background grid. The pressure in mm Hg was also recorded on the film. At the 50-ml rate of filling the bursting of the segment occurred in a fraction over one second (approx. 60 ml); the bursting vol. was 60 ml at the other two rates. This vol. was quite constant for the various segments of ileum tested. The internal diameter of the segment was obtained by subtracting 2 mm from the external diameter. At 2 ml/min. rate of water flow (28 tests) av. bursting pressure in mm Hg was 302; at 12 ml/min. (28 tests) av. bursting pressure was 343 mm Hg; and at 50 ml/second (26 tests) av. bursting pressure was 566 mm Hg. The bursting pressures at 2 different rates of flow (2 and 12 ml/min.) at the anastomoses were only slightly less than for the intact ileal wall (296 and 326 mm Hg).

- 10227 SUPERIOR MESENTERIC ARTERIOVENOUS FISTULA FOLLOWING SMALL BOWEL RESECTION (E.) Grafe, W. R. (New York Hosp.-Cornell Med. Ctr., N. Y.) and I. Steinberg. Gastroenterology 51(2):231-235, 1966.

Superior mesenteric arteriovenous fistula was diagnosed in a 67-yr.-old woman who had previously undergone small intestine resection when a continuous bruit, audible over the entire abdomen, was found along with a palpated thrill in the same area. The abdomen was protuberant, with dullness in the flanks, shifting dullness and a fluid wave. The woman complained of vague abdominal pain and increasing abdominal

ALL INTESTINE

birth of 6 wk. duration. A percutaneous right femoral selective superior mesenteric arteriographic study revealed a huge mesenteric arteriovenous fistula. Laparotomy disclosed an aneurysm at the root of the small intestine mesentery measuring about 1 cm in diameter. The afferent and efferent limbs of the fistula were ligated without compromising the intestine and the entire fistula was excised; the portal pressure fell from 42 cm of saline to 24 cm. There were no complications and the patient remains well to date. This is the eighth reported case of mesenteric arteriovenous fistula; 3 of those previously reported also followed small intestine resection.

- 228 AGANGLIONOSIS OF THE SMALL INTESTINE. (E.) Walker, A. W. (Washington U. Sch. Med., St. Louis, Mo.), R. L. Kempson and J. L. Ternberg. Surgery 60(2):449-457, 1966.

The literature contains 31 documented cases of aganglionosis involving the entire colon and a segment of the small intestine. Four cases were brought to the St. Louis Children's Hospital during 1965. All were infants at most only a few days old. Vomiting was general. Colonic activity was minimal or absent, except for a brief time in one infant. Operations to relieve the situation were performed; (1) ileostomy, (2) transverse colostomy, (3) ileocecal valvotomy, (4) ileotomy, ileostomy and right colectomy. The infants became infected; 2 suffered from peritonitis, 1 from Pseudomonas septicemia, and 1 from bronchopneumonia. All died very young; 12 days, 3 wk., 1 mo., 6 wk. Postmortem examination revealed that all had aganglionic colon; one had 12 cm of the distal ileum aganglionic; another had no ganglia in the last 20 cm of the ileum; a third had no ganglia from the anus to a level in the distal duodenum. The area of functional obstruction or of the aganglionic region begins at the anus and extends proximally for varying distances. The venting of the intestine should be done in a region where ganglionic cells are normal as determined by frozen section biopsy. Definitive surgery may be performed at a later time. Mortality is high (76% of the cases reported in the literature).

- 229 RECONSTRUCTION OF NORMAL JEJUNAL BIOPSIES: THREE-DIMENSIONAL HISTOLOGY. (E.) Cocco, A. E. (Johns Hopkins Hosp., Baltimore, Md.), M. J. Dohrmann and T. R. Hendrix. Gastroenterology 51(1):24-31, 1966.

The structural details of the intestinal mucosa can be better understood from three-dimensional reconstructions than from serial sections viewed under the microscope. Three different bioptic specimens were obtained from individuals without intestinal disease. When embedded in paraffin these tissues were carefully oriented, and 2 holes were made in the edges of each specimen with a heated 27-gauge needle. These holes served as reference guides during reconstruction. One specimen was sectioned at 10 microns in a plane perpendicular to the mucosal surface. The reference holes were aligned with a crosshair marker in the optical system; serial microphotographs were obtained; these were printed on transparent plastic plates, the thickness of which had the same ratio to the thickness of the tissue section as the plane dimensions of the photograph had to the respective dimensions of the section. The outline of the image on each plate was cutout on a bandsaw. The other 2 specimens were serially sectioned. When completed the sections were projected on velum of the proper thickness and traced. The cutout tracings were then assembled in correct order. Details of structure and relationships of the crypts of Lieberkühn, the transitional zones, circumvillar basins and the villi became clear; the villi in all 3 specimens were varied in shape from fingers, leaves or tongues to short ridges.

- 230 BIOSYNTHESIS OF INTESTINAL MUCIN IN SHOCK: RELATIONSHIP TO TRYPTIC HEMORRHAGIC ENTERITIS AND PERMEABILITY TO CURARE. (E.) Bounous, G. (McGill U., Montreal, Canada), A. H. McArdle, D. M. Hodges, L. G. Hampson and F. N. Gurd. Ann. Surg. 164(1):13-22, 1966.

Specimens of dog small intestine fixed in vivo showed a significant reduction in mucin production, particularly visible at the tips of the villi, which appears after 4 hr. of severe hypovolemia when signs of irreversible shock begin. When 45 mg d-tubocurarine chloride (curare) was inj. into such an intestinal loop which had been protected against tryptic hemorrhagic necrosis by inj. of Trasylol, all dogs

SMALL INTESTINE

died of poisoning within 45 min. The same treatment without the severe hypovolemia caused no deaths. The intestinal permeability seen during shock also occurred after local total intestinal ischemia or application of cyanide. Atropine, which specifically inhibits production of mucus by preventing acetylcholine from acting on the cell, also allows the osmosis of curare across the intestinal mucosa in amounts sufficient to produce death. These data indicate that the loss of mucus production seen late in hemorrhagic shock is a possible pathogenic factor in rendering the intestinal mucosa accessible to unphysiologic and physiologic poisons, as well as to proteolytic digestive enzymes.

- 10231 EFFECTS OF BACTERIAL FLORA ON SURVIVAL OF RATS WITH STRANGULATION OBSTRUCTION. (E.) Armstrong, J. R. (Louisiana State U. Sch. Med., New Orleans), J. B. Heneghan and G. H. Bornside. Bull. Soc. Int. Chir. 25(2):108-113, 1966.

Gnotobiotic and germ-free Sprague-Dawley rats survived an av. of 4-9 times longer than conventional rats following strangulation obstruction of the ileum. The intestinal flora of the gnotobiotic rats consisted of Clostridium sordelli, Serratia species, both of these, Escherichia coli and serratia sp., or Staphylococcus aureus, bacillus sp. and penicillium sp. The animals harboring both E. coli and Serratia survived the longest, 9 times longer than the conventional rats and twice as long as the germ-free ones. The post-mortem appearance of the strangulated loop (an obstruction of the ileum 10 cm from the cecum) in all of the gnotobiotic animal categories was identical with no mesentery congestion and differed only slightly from the remainder of the small intestine. In contrast, the loop in the conventional animal was very cyanotic or frankly necrotic with marked congestion of the strangulated portion of the mesentery. All surgery and observations were performed within an isolator system.

- 10232 THE ACTION OF THE FOLIC ACID ANTAGONIST METHOTREXATE (AMINOPTERIN) ON THE REGENERATION OF THE INTESTINAL MUCOSA. (Ger.) Eder, M. (U. Munich, Germany), H. Rostock and G. Vogel. Virchow Arch. Path. Anat. (341):164-176, 1966.

Mice (28) received 0.5 ml of aminopterin (A) daily (12 µg/100 g body wt.) by stomach tube in a chronic study (8 wk.); animals were killed after 4, 8, 14, and 21 days; half of the animals were inj. i.p. with 0.3 µc H³-thymidine, 1 hr. before death; the other half was inj. with thymidine 48 hr. prior to death; one animal treated with A for 14 days received radioactive thymidine 24 hr. before being killed. For the acute studies, 30 mice each received i.m. 400 µg/100 g body wt. in one dose of A; the animals were killed at 4, 8, 16, 24, 48, 72, and 144 hr. All were inj. with 0.3 µc H³-thymidine, 20 mice 1 hr. before death; 2 mice killed after the 24-hr. experimental period received thymidine 1 hr. after A admin.; those killed at 48, 72, and 144 hr. received thymidine 24 hr. prior to death. Tissues were removed from the duodenum 1 cm below the pylorus, the jejunum 18 cm proximal to the ileocolic valve, ileum 1 cm proximal to the ileocolic valve, ascending colon 1 cm in the right limb, and in the descending limb 1 cm beyond the flexure, and studied by optical microscopy and autoradiographically. No significant differences in alkaline phosphatase were observed in the brush borders in any of the normal or experimental animals. In the chronic experiments the villi slowly atrophied, especially in the duodenum and was related to some cellular loss in the zone of regeneration. Acute admin. of A damaged the regeneration zone. The viable cells remaining after the massive dosage showed increased synthesis of DNA. Four days later the zone of regeneration was almost restored by cell proliferation. During the repression of the regenerative zone, the migration of cells to the villi was interrupted or delayed. After restoration of the zone, renewal of villous cells was accelerated. In the ascending and descending colon where renewal of cells was slower than in other parts of the intestine, the effect of A appeared in a diminished form as a repression or block of short duration.

- 10233 DISACCHARIDASE ACTIVITY OF THE DUODENAL MUCOSA IN THE NORMAL CHILD. (It.) Lamedica, G. M. (U. Genoa, Italy), L. Vignolo, A. Berio and S. Nordio. Minerva Pediat. 18(14):704-720, 1966.

ALL INTESTINE

even children (6 mo.-3 yr.-old) recovering from trivial acute disorders were studied. Intestinal biopsies were taken and disaccharidase activity of the intestinal mucosa was determined by the (modified) chromatographic method of Auricchio. Protein was determined using the Folin-Ciocalteu method and enzymes with the TRIS-alkaline phosphatase method of Dahlquist (except that the Boehringer glucose-test method of Schmidt was used for maltase). Disaccharidase activity is reported in U/g of protein of wet mucosa. Maltase activity varied from 198-434 (mean 277), saccharase from 45.6-148 (mean 89), isomaltase from 43.2-142 (mean 81.5), and lactase from 1.6-54 (mean 32.7). Maltase activity is always the highest and lactase activity the lowest. Because saccharase and isomaltase activities are always about the same, both activities could be dependent upon the same enzyme. The authors conclude that because of the variability of values in normal children and the possibility that the enzyme activity is readily modified by many factors, one must be careful in evaluating pathological decrease in activity.

- 234 "FERTILE" INTESTINE NUCLEI. (E.) Gurdon, J. B. (Oxford U., England) and V. Uehlinger. Nature (London) 210(5042):1240-1241, 1966.
Cells from the differentiated intestinal epithelium of Xenopus laevis tadpoles which had just begun to feed were dissociated and their nuclei transplanted into unfertilized ova enucleated by UV irradiation. The epithelial cells, from which the nuclei were obtained, were columnar with a striated border for absorption; about 10% of these epithelial cells were gland cells. The embryos and tadpoles which grew to frogs were normal as larvae and the adult frogs did not differ from other frogs reared in the laboratory. The somatic cells were diploid with one nucleolus per nucleus. When mature these frogs were mated to wild-type frogs and to other clear transplant frogs. The females produced the number of eggs usual for frogs reared in the laboratory. The F₂ generation was no different from the usual laboratory frog. The processes involved in permitting the activity of those genes required for the differentiation of an intestinal cell and in repressing those not required, cannot therefore entail the irreversible loss or inactivation of genes needed for the differentiation of other cell types.

- 10271 SURGICAL DUODENAL ULCER. A DISEASE ENTITY? (E.) Buckwalter, J. A. (State U. Iowa Coll. Med., Iowa City) and L. Raterman. Arch. Surg. (Chicago) 93(1):154-160, 1966.

A statistical study was made of the records of 700 patients operated upon for duodenal ulcer to test the hypothesis that duodenal ulcer is a common clinical denominator of an unknown number of disorders and not a single disease entity. The main groupings were in terms of the 4 chief indications leading to surgery: a) perforation, b) intractability, c) bleeding, d) pyloric obstruction. Sex-differentiated patients were listed under the chief indications and each one of the following categories: 1) age, 2) chief complaint of patient, 3) pain pattern, 4) other symptoms and patterns, 5) duration of symptoms prior to surgery, 6) disability, 7) gastric analyses, fasting and histamine, 8) blood grouping. Some of the more salient findings from these cross comparisons were: patients with intractable ulcer fell into the youngest age group; those with pyloric obstruction into the oldest age group. Patients with bleeding ulcer had the shortest symptomatic period before surgery; those with intractable ulcers had the longest period. Long-term prognosis seemed best in patients operated on because of bleeding, and worst in those operated on for perforation. It also appeared that the male:female ratio of ulceration was 5:1; perforation in men was twice that in women. The male patients were younger, had symptoms longer before operation, more frequently had typical ulcer pain, bled less often and less severely than women.

- 10272 SOCIAL STRESS AND LIVING HABITS IN THE ETIOLOGY OF PEPTIC ULCER. (E.) Kasanen, A. (U. Turku, Finland) and J. Forsström. Ann. Med. Intern. Fenn. 55(1):13-22, 1966.

Gastric (43) and duodenal (57) male employed ulcer patients ranging in age from 23-64 yr. were compared with 100 male non-ulcer patients ranging in age from 19-63 yr; the groups of patients were from approx. the same social groupings. Some comparisons were made with 100 comparable myocardial infarction patients. A special questionnaire was used to collect the data. Marital status and childhood experiences, financial status and conditions of work were similar for the 3 groups. Ulcer patients were more often self-employed or held temporary jobs and were more frequently worried about their economic status and more often did not take an annual holiday because of work. Ulcer patients ate less frequently than controls, smoked more, drank more coffee, and used analgesics more often. There was no significant difference in the consumption of alcohol.

- 10273 PROGRESS IN PATIENTS WITH PEPTIC ULCERATION TREATED FOR MORE THAN FIVE YEARS WITH POLDINE, INCLUDING A DOUBLE-BLIND STUDY. (E.) Hunt, J. N. (Guy's Hosp. Med. Sch., London) and R. C. Wales. Brit. Med. J. 2(5504):13-16, 1966.

Poldine (8-44 mg/day) and placebo were compared under double-blind conditions in 10 patients with duodenal ulcers and 2 with gastric ulcers for a period of 3 yr. preceded by a 3-mo. period when all patients received poldine. After 6 mo. the control and drug groups were exchanged. Acid, bicarbonate and pepsin secretion were studied with test meals monthly throughout the study. Gastric secretion in patients treated for long periods with poldine decreased and did not rise when they were switched to inactive tablets. Poldine reduced both acid and pepsin response to test meals; gastric emptying was slowed by 10%; this latter effect during long-term treatment disappeared. Undesirable toxic actions on bone-marrow, liver, or kidney or effects on intraocular pressure were not detected. It is concluded that since poldine reduces gastric secretion by half, as does vagotomy, it might well be considered for the treatment of duodenal ulceration.

- 10274 PRODUCTION, BY RESTRAINT, OF GASTRIC ULCERS AND OF HYDROTHORAX IN THE RAT. (E.) Robert, A. (Upjohn Company, Kalamazoo, Mich.), J. P. Phillips and J. E. Nezamis. Gastroenterology 51(1):75-81, 1966.

Female rats with an av. body wt. of 205 g were restrained in pliable window screen fastened with staples. No anesthesia was used and the paws were kept within the

een. The animals were fed and given water up to the time of restraint except in the effect of fasting was studied. The animals were usually restrained for 8 hr.; the animals were killed by chloroform. The chest was opened and the accumulated fluid was measured. The stomach was excised and examined under 2 times magnification for ulceration. Two groups of rats were restrained for 8 and 24 hr.; each group were subgroups fed until the time of restraint and subgroups fasted at various intervals prior to restraint. In both groups fasting reduced ulceration, the reduction increasing with the duration of fasting. In restrained animals pleural fluid appeared at 4 hr. and was max. at 24 hr.; thereafter the vol. was reduced, indicating some reabsorption. At no time was there any ascites. When animals were fasted prior to restraint, pleural fluid was absent. Ulceration in fed animals increased with the time of restraint. When rats were kept under restraint for 24 hr. then released and kept under fasting conditions, 12 hr. after restraint degree of ulceration was the same as at release time; 24 hr. after release time degree of ulceration had dropped to half. Hydrothorax was unchanged at 6 hr., reduced at 12 hr. and completely resorbed at 24 hr. Other factors which affected restraint ulceration and hydrothorax were: crowding of animals, rise of ambient temperature, and administration of prednisolone (inhibition). An anticholinergic inhibited ulceration but not hydrothorax, whereas adrenalectomy inhibited hydrothorax but not ulceration.

75 BRAIN TRAUMA AND THE DEVELOPMENT OF ULCER DISEASE. (Rus.) Kalienik, N. I. (Regional Neuropsych. Hosp., Mogilev, USSR). Vrach. Delo (6):129-130, 1966. Evidence for a possible etiologic role of cerebral trauma in the development of peptic ulcer disease was sought in studies on 300 invalids wounded in the last World War, 150 of whom had suffered closed, and 93, open, head injuries. Observations made in 1945-57 disclosed 29 cases of peptic ulcer, and 5 more cases were discovered later among those members of the original group who were followed up for 8-10 yr. Thus ulcers were found in 34 (11.3%) of the whole sample (gastric in 8, duodenal in 25, gastroduodenal in 1). This percentage is significantly greater than the pre-war figure of 1.7% of all hospitalized men reported from Leningrad and suggests a causal connection between the cerebral trauma and the ulcer. Other possible contributory factors (psychic trauma, emotional stress, faulty eating habits, excessive smoking, etc.) cannot be ruled out. In only 1 case had a diagnosis of ulcer (duodenal) been made before the head injury, and in only 2 cases had gastritis been diagnosed prior to the injury. The interval between the trauma and the appearance of the ulcer was short (6 mo. or less) in only 2 instances; in most cases, the ulcer did not develop until much later in the post-traumatic period.

76 ELECTROLYTE COMPOSITION OF THE BLOOD AND POTASSIUM LOADING TEST IN GASTRO-DUODENAL ULCER. (Rus.) Vainshtein, S. G. (V. I. Lenin Inst. Postgrad. Med. Train., Kazan, USSR). Ter. Arkh. 38(5):26-30, 1966. Mineralocorticoid function was indirectly explored in 98 patients with normo-, hypo-, or hyperacidic gastritis, 111 with duodenal ulcer, 28 with gastric ulcer. 3 tests employed were the Robinson-Power-Keppler test, determination of the Na/K ratio, and a modification of Bojanowicz's potassium loading test (1 ml/kg p.o. of 4.8% soln. of KCl = 25 mg/kg K). Flame photometry was used to determine the blood and plasma Na and K levels in fasting subjects and after K loading. A rise in the whole blood K conc. of more than 1.2 mEq/liter and a rise in the plasma K conc. of more than 0.12 mEq/liter were regarded as reliable indicators of an elevated K level and hence of inadequate adrenal mineralocorticoid function. Such results were observed 1 hr. after loading both in patients with ulcers and in those with hyperacidic gastritis, thus supporting Bojanowicz's view of ulcer disease as a clinical form of mineralocorticoid deficiency and of hyperacidic gastritis as a peptic ulcerous condition. The changes in plasma K conc. observed in the various groups after loading were not significantly different, but the increase in whole blood K conc. reliably differentiated between patients suffering from exacerbations of duodenal ulcers with demonstrable niches and those with hypo- or hyperacidic gastritis. In patients who gave a positive response to the loading test, the hyperkalemia was accompanied by hyponatremia and lowering of the Na/K ratio. This combination of hyponatremia and hyperkalemia is a characteristic indication of reduced aldosterone production or activity.

- 10277 THE PRESENCE IN ULCER PATIENTS OF ANTIBODIES TO ANTIGEN PREPARED FROM HUMAN GASTRIC AND DUODENAL MUCOSA. (Rus.) Grinshpun, O. Ia. Ter. Arkh. 38(5):30-32, 1966.

In an attempt to demonstrate anti-gastric and -duodenal mucosa antibodies in patients with ulcer, antigens were prepared from the gastroduodenal mucosa of patients undergoing surgery for complications of ulcer disease and from that of a healthy individual killed in an accident. Sera from the patients were studied with the complement fixation reaction and Boyden's passive hemagglutination reaction. Of the 458 persons investigated, 165 had ulcer disease (152 with niche, 13 in remission); 172 persons suffering from a variety of other diseases and 121 healthy donors served as control groups. Antibodies to gastric and duodenal mucosa were demonstrated in 90.8% of the patients with ulcer in the niche phase, as compared with 11.5% of those with miscellaneous diseases (5 each with chronic cholecystitis, rheumatism, and neurocirculatory dystonia) and only 4.1% of the healthy subjects. Positive results in the complement fixation test usually paralleled positive results with the passive hemagglutination reaction, but the latter test was more sensitive, yielding positive results in 8 cases in which the former gave negative results. In only 1 of the 13 patients with "quiescent" ulcers were anti-mucosa antibodies demonstrable, and in many of the others, formerly positive reactions became negative when the ulcers had healed. The antibodies demonstrated were specific for the gastroduodenal mucosa and did not react with antigens prepared from other human organs. Just what role they may play in the pathogenesis of ulcers remains to be determined.

- 10278 SELECTIVE GASTRIC VAGOTOMY VERSUS TOTAL ABDOMINAL VAGOTOMY. (E.) Hedenstedt, S. (Gen. Hosp., Nacka, Sweden) and G. Lundquist. Acta Chir Scand. 131(6):448-459, 1966.

Fifty patients underwent selective gastric and 30 patients total abdominal vagotomy for various ulcer conditions. In 20 gastric and 47 duodenal ulcer cases, vagotomy was combined with partial gastric resection and jejunal transposition, and in 10 dumping cases it was combined with secondary jejunal transposition. With 3 stomal ulcer cases only vagotomy was performed. Forty-four patients underwent bilateral selective vagotomy; six, anterior selective and posterior total vagotomy; the rest total vagotomy. The patients were followed up 6 mo. to 2 yr. later and Hollander Insulin Test (1946) was used to assess completeness of vagotomy. Forty-two of 44 patients treated with bilateral selective procedure had complete vagotomies with other 2 possibly regarded as complete. All 6 cases treated with anterior selective and posterior total vagotomy were complete. Twenty-seven of the 30 total vagotomies were complete with 1 of the other 3 possibly regarded as complete. Four of 50 patients with selective vagotomy (8%) had mild diarrhea. Fifteen of 30 patients with total vagotomy had diarrhea (mild in 6, moderate in 7, and severe in 2 cases). In the dumping group, diarrhea was present in 17% after total vagotomy and in 4% after selective vagotomy. In the group with diarrhea alone (no dumping), the incidence was 33% after total vagotomy and only 4% after selective vagotomy. Dumping occurred in 14% after selective vagotomy and 23% after total vagotomy. No ulcer recurrence was noted, but the interval since operation was too short for evaluation.

- 10279 EARLY AND LATE RESULTS OF THE TREATMENT OF PERFORATING PEPTIC ULCER. (Rus.) Petrov, A. F. (Belgorod Regional Hosp., USSR). Vestn. Khir. Grekov. 96(5):17-20, 1966.

Analysis of the clinical features and late results of surgery in 933 patients (899 male, 44 females) with perforated gastric and duodenal ulcers seen from 1948. Perforation occurred most often in the mo. of May and June, rarely in November to January; most often between 4 and 6 P.M., rarely between 4 and 5 A.M. In 41 of the cases, it occurred during physical exertion; in 25.2%, after eating a meal or drinking alcohol; in 24.8% during sleep or while resting in bed. In 2 cases it occurred shortly after X-ray examination, and in 3 cases, during the study of gastric secretion. Hospitalization was prompt in 58.6%, but the diagnosis at admission was correct in only 43.2%; it was incorrect in 22.3% of the younger patients and in 60.0% of the older patients. The overall mortality was 8.9%; the postoperative mortality was 7.9% and was directly correlated with the time of hospitalization. No explanation

can be offered for the high mortality in women: 20.4%, as against 8.3% in men. The results are available for 356 (41.9%) of the patients who underwent surgery. Simple suturing of the ulcer was done in 84.21%, with poor results in 85.2% and a mortality of 7.1%. Suturing + gastroenteroanastomosis was done in 8.9%, with poor results in 84.3% and a mortality of 10.8%. Primary gastric resection, done in only 6 cases (6.2%), gave good or satisfactory results in all. It is definitely the treatment of choice and should replace palliative procedures. Of the patients undergoing palliative surgery, 148 (52.3%) had to have a further operation. Gastrectomy was performed in 117 of these cases, and there were 2 postoperative deaths after the second operation.

280 DUODENAL ULCER IN SUBTROPICAL REGIONS. (Cz.) Holubec, K. (Lula Rasa Makonnen Hosp., Harar, Ethiopia). Čas. Lék. Česk. 105(20):524-529, 1966. Duodenal ulcer in Ethiopia occurs very frequently. Its high incidence has been ascribed by some to the common use, here as elsewhere in North Africa, of the leaves of Catha edulis Forsk ("kath"), either chewed fresh or ground and mixed with sugar. The drug contains a number of alkaloids with complex action (predominantly ephedrine-like); it induces euphoria and reduces fatigue and hunger sensations, but may also give rise to schizophrenic symptoms and homicidal mania. Drugs of similar complexity are, of course, known to affect heart action and intestinal peristalsis, but the importance of "kath" in the development of gastroduodenal ulcer is doubtful, since it is used only by Muslims, whereas this same type of ulcer is also common among Christian Ethiopians, who prefer alcohol, not "kath." The author is more inclined to incriminate a hot spice used in food preparation throughout Ethiopia and North Africa generally, by Muslims and Christians alike. Whatever their cause, these "Ethiopian" ulcers are characterized by their unusual localization and extension: they are always found on the posterior wall of the duodenum and impinge on the head of the pancreas. This peculiar location means that they cannot be handled with the usual surgical technic, and the author, seeing no need for vagotomy, used Porges's method to close the duodenal stump in his 39 patients, all of whom made an eventful recovery.

281 AGE, WEIGHT, AND SOCIAL EFFECTS ON ULCERATION RATE IN RATS. (E.) Sawrey, J. M. (San Jose State Coll., California) and W. L. Sawrey. J. Compar. Physiol. Psychol. 61(3):464-466, 1966. Rats were placed in a "conflict" situation for 14 days singly, in pairs, or groups of 3. The apparatus was arranged so that approaches to food and water were shocked for 23 hr./day. After 5 days of this procedure 47 hr. of shock followed by 1 hr. of free access to food and water were followed for 10 days. All the rats were killed and ulcers identified. The av. number of ulcers for single rats was 9.13; paired rats, 1.75; and 3 to a box, 1.26. There was no significant wt. loss between the 3 groups. A second experiment followed the same procedure except that all rats were tested singly. Groups of rats 84, 124, and 164 days old divided into subgroups by sex were compared. Neither age nor wt. significantly affected the number of ulcers seen in the 84- and 124-day-old rats. The heaviest rats of the 164-day-old group ulcerated at a higher rate than any of the other groups. These data are consistent with previously reported findings that rats in groups ulcerate at a lower rate than rats tested singly.

82 NEOPLASTIC CHANGE IN CHRONIC GASTRIC ULCER. STUDY OF ULCERS AND CANCERS OBSERVED IN SURGICAL AND NECROPSY MATERIAL. (It.) Benbanaste, M. (Numane Haydarpascia Hosp., Istanbul, Turkey). Gior. Ital. Chir. 21(6):779-792, 1965. Contradictory opinions have been expressed for secondary neoplastic change in chronic gastric ulcers and are probably due to divergence of clinical and radiologic techniques used. Histological examination is valid in an early stage transformation and diagnosis, but the origin of the peptic ulcers is completely cancelled in later stages prohibiting evaluation as a primary or secondary cancer. A histological examination of 2722 resected stomachs revealed 1806 simple peptic ulcers, 867 primary cancers and 49 degenerated ulcers; neoplastic changes were seen in 2.72% and 56% resp. Histological autopsies of 198 patients who died of stomach cancer

revealed 41 tumors (20.7%) with a peptic ulcer origin. Males appeared to be more susceptible to ulcer cancers than females (80% and 19%, resp.); the most frequent age group is between 35 and 69. Most of the malignancies were seen in the greater curvature of the stomach. Stomach perforation, hemorrhage and stenosis were frequently observed complications.

Regional Enteritis

- 321 CORTICOSTEROIDS AND CORTICOTROPHIN IN THE TREATMENT OF CROHN'S DISEASE. (E.) Jones, J. H. (Central Middlesex Hosp., London) and J. E. Lennard-Jones. Gut 7(2):181-187, 1966.
- Initial improvement occurred in 22 of 30 patients with Crohn's disease when they were treated with corticosteroids or ACTH without antituberculous therapy. All 22 patients received at least 40 U of ACTH or the equivalent of 100 mg of cortisone daily for a minimum of 3 wk. Aside from mooning, the two most common complications during treatment were fecal fistula (15 cases) and pancreatitis (8 cases). However, the later outcome of these patients was less favorable: only 3 required further therapy; 7 are maintained in fair or good health by long-continued corticosteroid therapy; 8 have been treated by resection; and 4 have died. The results in a group treated with antituberculous drugs in addition to corticosteroids and ACTH were little different from those already discussed, but the number (7) of patients was too small to be conclusive.
- 322 JEJUNO-ILEAL FISTULA FOLLOWING SURGERY FOR TERMINAL ILEITIS. DIAGNOSIS BY PROTECTED JEJUNAL INTUBATION. (Fr.) Mainguet, P. (U. Saint-Pierre, Brussels, Belgium), O. Thys and A. Bremer. Acta Gastroent. Belg. 29(3):356-364, 1966.
- 323 COMPLICATIONS IN CROHN'S DISEASE. (Rus.) Duberman, L. B. (Sokol City Hosp., Vologod Region, USSR). Vestn. Khir. Grekov. 96(5):100-102, 1966.

- 10324 XYLOSE ABSORPTION IN MENTALLY RETARDED CHILDREN. (E.) Chapman, M. J. (Queen Mary's Hosp., Carshalton, Surrey, England), P. M. Harrison and J. Stern. J. Ment. Defic. Res. 10(1):19-26, 1966.

Xylose absorption was studied in 40 children (16 with Down's disease, 20 unclassified, the remaining 4 diagnosed as Sturge-Weber syndrome, hydrocephalus, microcephaly and post-vaccination encephalitis). Age range was 3-14 yr., av. age 9 yr. 5 mo. For urinary excretion tests 0.5 g/kg xylose was admin. p.o. as 10% soln.; urine was collected for two 5-hr. periods. For blood levels 10 g/mg body surface xylose were admin. p.o. Higher doses of xylose were refused or produced diarrhea. Capillary blood samples were taken at 30 and 60 min. Blood and urine xylose were estimated by Roe and Rice's method. Av. urinary excretion of xylose in 21 children was 28%, significantly lower than the normal 32-40%. Blood xylose levels for 34 children (24.4 and 33.3 mg/100 ml at 30 and 60 min.) were significantly lower than normal (31.4 and 51.8) at 60 min. There was no significant difference between patients with Down's disease and the other retarded children. It is suggested that changes in intestinal mucosa as well as possible defects in CNS control of luminal resistance might, in part, explain these findings. It appears that the basic absorptive mechanism for xylose is intact but that its capacity is readily exceeded.

- 10325 LYMPHORETICULAR DYSFUNCTION IN IDIOPATHIC STEATORRHOEA. (E.) McCarthy, C. F. (Royal Infirm., Bristol, England), I. D. Fraser, K. T. Evans and A. E. Read. Gut 7(2):140-148, 1966.

Twenty-five patients with idiopathic steatorrhea (confirmed by biopsy), 29 with celiac disease (16 histologically verified, 13 had presenting symptoms and favorable response to a gluten-free diet), 50 post-splenectomy patients and 25 peptic ulcer patients (controls) were studied. RBC were studied for Howell-Jolly bodies, serum B12 levels were determined, serum folate levels were measured. Patients were given oral loading dose of histidine, urinary Figlu detected by electrophoresis. Inguinal lymph glands were obtained from some patients for study. In selected patients RBC were labeled with Cr⁵¹, sensitized with anti-D serum and reinjected; blood samples were examined periodically. Spleen size was studied radiographically, or at surgery and necropsy. Serum antibodies were estimated following inj. of T.A.B. antigen. Howell-Jolly bodies were found in the red blood cells of 5 of 25 steatorrhea patients but in none of the controls or celiac disease patients. Cells of splenectomy patients contained Howell-Jolly bodies ranging from 0.0001% to 3.1%. RBC survival time in steatorrhea patients with Howell-Jolly bodies was prolonged, in those without, normal. The normal increase in splenic counting after inj. of Cr⁵⁹-tagged damaged cells was absent in the first group of patients or following splenectomy. Lymph gland abnormalities were found in steatorrhea patients; no marked change in titer of 0 antibodies developed following T.A.B. vaccine. Three steatorrhea patients were found to have unusually small spleens. The clinical and biochemical features of the patients with and without atrophy of the lymphoreticular system did not differ. Whether or not such atrophy is of clinical significance was left unanswered. Three case studies were presented.

- 10326 DISCORDANCE FOR NONTROPICAL SPRUE (ADULT CELIAC DISEASE) IN A MONOZYGOTIC TWIN PAIR. (E.) Hoffman, H. N. II. (Mayo Clinic, Rochester, Minn.), E. E. Wollaeger and E. Greenberg. Gastroenterology 51(1):36-42, 1966.

A 54-year-old, white, unmarried, female office worker was seen in Nov., 1962 for low back pain. She was thin and since childhood had been a few pounds lighter than her identical twin sister. Over a period of 8-10 yr. she had suffered intermittent mild diarrhea. Physical findings and laboratory data were normal except for a sternal depression. Biopsy of the proximal jejunum disclosed subtotal villous atrophy and hyperplasia of crypt portions with increased mitosis of crypt epithelium. The staining was abnormal and there was no brush border on epithelial cells. The overall appearance was that of untreated non-tropical sprue. She was instructed in a gluten-restricted diet and advised to take a multiple vitamin per day. In May, 1964, her general condition indicated some reversion toward normal. In August, 1964, the findings were the same as those on the previous visit. A biopsy of the jejunum

wed improvement similar to that experienced on a gluten-free diet in a case of tropical sprue. The patient's sister was examined and although the two sisters lived together all their lives, the jejunal mucosa of the sister proved to be normal as were all other findings and laboratory data. Twin studies were then made. The close similarity in multiple physical characteristics, menstrual history, etc., support the hypothesis of monozygosity.

- 27 TROPICAL SPRUE: VIRAL CULTURES OF RECTAL SWABS. (E.) Bayless, T. M. (U. Puerto Rico Sch. Med., San Juan), A. Guariola-Rotger and M. S. Wheby. Gastroenterology 51(1):32-35, 1966.

Two groups of subjects were studied: Group 1: All 50 patients were either untreated or without therapy for the preceding 5 yr. Ages ranged from 15-75 yr.; were Puerto Ricans from low income groups and 16 servicemen or their dependents. The diagnosis of tropical sprue was based on clinical evidence, i.e. diarrhea and weight loss and laboratory evidence such as abnormal fat and xylose absorption, megaloblastic anemia or changes in bone marrow consistent with low folic acid or B₁₂. Group 2: Tropical sprue in remission at least 1 yr. (10 patients). Group 3: Controls (48 asymptomatic, healthy Puerto Ricans over 16 yr. of age): Throat and rectal swabs were obtained upon first visit or within 3 days of admission. Acute serum was obtained at this time, convalescent sera 3-6 wk. later. All specimens were stored at -70°C. The technique for isolation of enteroviruses employed tissue cultures of amnion cells, monkey kidney, and HEp-2 cell cultures. The inocula were prepared, the cells inoculated and growth medium substituted for the inoculating medium. The tubes were watched for cytopathogenic effects. Four uninoculated cell cultures were incubated with the test cultures to check for latent viruses. Enzyme passage passages were run when slight cytopathogenic effects were noted. Suckling mice intracranially inoculated were also used to isolate viruses. Isolated viruses were identified by neutralization using pooled antisera. A virus was isolated from one of the 50 patients in Group 1 and identified as Cocksackie B-3. A significant rise in antibody titer was observed. One of the 10 patients in Group 2 had a positive rectal swab (Cocksackie B-3). A virus (ECHO-8) was obtained from 1 member of the control Group 3. Those data constitute essentially negative results as for a direct viral causation of tropical sprue.

- 28 EFFECT OF ANTIBIOTIC THERAPY ON GLUTEN-SENSITIVE ENTEROPATHY. (E.) Roufail, W. M. (Duke U. Med. Ctr., Durham, N. C.) and J. M. Ruffin. Am. J. Dig. Dis. 11(8):587-593, 1966.

A patient with diagnosed nontropical sprue was given gluten-free diet and in 3 wk. clinically improved, although mild diarrhea persisted. Two yr. later the patient was readmitted with exacerbation of diarrhea and found to have deficiency of sucrase, lactase, and maltase. A gluten-free diet with restriction of milk and fruit juices was unsuccessful. Tetracycline, 250 mg 4 times/day, and gluten-free diet were tried for 1 mo. with clinical improvement. This therapy was continued for 4 more mo. with the patient asymptomatic with normal biochemical tests for sucrase and fat. Upon returning to regular diet and omitting tetracycline for 4 mo. the patient was asymptomatic even when challenged with gluten and the histology and absorption studies were normal. A patient with diagnosed sprue was treated with steroids and gluten-free diet and did well clinically for 6 years, but relapsed after discontinuance of treatment. The patient was admin. a gluten-free diet for 1 yr with cessation of diarrhea only to have gluten challenge cause exacerbation of diarrhea. Patient was placed on gluten-free diet with calcium and vitamin D and experienced clinical recovery. On later admission all tests were normal except sucrase. Tetracycline, 250 mg/4 times/day, was added to regimen. In 2 mo. the sucrase-free diet discontinued; tetracycline was continued. One mo. later biochemistry was normal even with gluten challenge, but histology was unchanged. The regular diet and tetracycline continued and the patient was asymptomatic, but histology unchanged. The response to antibiotic therapy in these cases suggests that bacteria may be involved in gluten-sensitive enteropathy.

- 29 THE ENZYMATIC DETERMINATION OF LACTIC ACID IN FAECES IN GLYCOSIDASE DEFICIENCY. (E.) Clarke, A. D. (Sheffield Child. Hosp., England) and D. A. Podmore. Clin. Chim. Acta 13(6):725-730, 1966.

SMALL INTESTINE

The method employs an acid alcohol extraction of fecal matter with ultrafiltration of the supernatant fluid. Spectrophotometry is then performed on the ultrafiltrate. It is imperative that the fresh fecal specimen be placed in a preservative immediately. Fecal lactic acid conc. are presented for 24 normal healthy children 1 wk.-9 yr. old, 17 children hospitalized for various conditions, ages 1 wk. to 9 yr. old and 1 child with lactase deficiency, age 2 wk. High values were found on occasions. The normal group showed a range from 3-120 mg lactic acid/100 g feces whereas, the hospitalized group ranged from 4-94 mg/100 g. In the case of glycosidase deficiency, the patient showed an inability to break down lactose. Its administration resulted in diarrhea and high conc. of fecal lactic acid (280 mg/100 g).

- 10330 PROTEIN-LOSING ENTEROPATHY WITH REMISSION DURING PREGNANCY. (E.) Hoffbrand, B. I. (Whittingdon Hosp., London). Proc. Roy. Soc. Med. 59(6):566, 1966.

The case history of a 32-yr.-old woman studied over a period of 12 yr. because of intermittent diarrhea, tetany, and ankle edema is presented. Laboratory studies revealed hypoproteinemia, hypocalcemia, aminoaciduria, and lymphopenia; jejunal biopsy was declined. During both of 2 pregnancies (yr. 2 and yr. 12), the patient was symptom-free, with serum protein values rising to almost normal; relapse within 1 mo. postpartum occurred both times. The author suggests that the increased serum proteins during pregnancy could be due either to fetal contribution or to the protein-binding properties of the sex hormones.

- 10331 INTOLERANCE TO GLUTEN. (It.) Vignolo, L. (U. Genoa, Italy), G. Vignola, G. M. Lamedica, A. Berio and S. Nordio. Minerva Pediat. 18(14):733-737, 1966.

Twenty-seven children (9 mo.-4 yr. old) with subacute to chronic diarrhea manifesting an intolerance to gluten as determined by the following criteria: (1) intestinal malabsorption, especially of fat and xylose; (2) flattening of the intestinal mucosa; (3) clinical and laboratory improvement on a gluten-free diet; (4) relapse upon re-introduction of gluten into the diet. All 27 patients improved on a gluten-free diet. Those who met all 4 criteria (8 patients) were diagnosed as having congenital intolerance to gluten; in 7 other patients in whom intestinal biopsy was not done, this diagnosis was considered probable. In the case of 5 patients, the authors declined to state the presence of a congenital intolerance because Criterion 4 was not carried out. An acquired and transitory intolerance was considered plausible in the last 7 patients who lacked data for both Criteria 2 and 4. In the 10 patients who had long-term follow-up, the intestinal mucosa and the xylosuria returned to normal in only 2 and 1 patients, resp.; improvement in blood glucose levels, intestinal X-rays, and normal values for serum cholesterol and proteins resulted in all those tested. The onset of symptoms in 5 patients prior to the inclusion of gluten in the diet demonstrates that other factors can initiate the disease in a predisposed patient. The authors conclude that intestinal lesions are reversible, but that lack of rigid adherence to diet plus other factors, e.g. folate acid deficiency, can hinder the reversal of anatomic changes in the face of clinical improvement. Abnormal duodenal biopsies and xylose tests do not preclude normal mucosa with good absorption distally; for this reason, patients under treatment or patients with initially limited lesions can have abnormal xylose tests without steatorrhea.

- 10332 INVESTIGATION OF FECAL SUGARS IN THE DIAGNOSIS OF STATES OF MALABSORPTION AND MALDIGESTION OF SUGARS. (It.) Lamedica, G. M. (U. Genoa, Italy), A. M. Martino, P. Durand and M. Buonvino. Minerva Pediat. 18(14):698-701, 1966.

Semi-quantitative determinations of sugar in the feces and urine of 164 children following oral loading doses of mono- or disaccharides (2 gm/kg) were made utilizing a chromatographic method of Lamedica in which chemically treated fecal suspension or urine is compared with a glucose standard. Among 20 patients with "metabolic enteropathy" (Group 1), galactose and/or lactose was found in the feces in 8: 5 patients with malabsorption syndromes and intolerance to lactose, 1 with celiac disease, 1 with fibrocystic disease of the pancreas, and 1 with primary

tolerance to lactose. In 7 of these and in at least 4 other patients, sugar was so found in the urine. No patients with dyspepsia or infectious diarrhea (Group 44 patients) had sugar in the feces and only 2 had urinary sugar. Four of 6 patients with *Giardia lamblia* infestations (Group 3) had lactose in the feces and none after oral feeding of that sugar. Fecal sugar was not found in any of 54 (Group 4) subjects without gastrointestinal disease. A transitory lactose intolerance was provoked in 10 normal children (Group 5) by giving them the lactose feeding for 2-4 consecutive days; all of these excreted lactose, galactose, or glucose in the feces concomitant with clinical sign of intolerance to disaccharides. In cases of sugar intolerance, the fecal sugar is found only after loading doses of undigested disaccharide and not after feeding of other, tolerated sugars. A prevalence of disaccharide relative to monosaccharide in the more severe cases was observed, and in fecal specimens examined at various times after the loading dose, glucose was found to disappear more rapidly than galactose. No correlation was found between the amount of sugar and that of lactic acid in the feces.

333 CONSIDERATIONS ON SOME CASES OF CHRONIC DIARRHEA NOT DUE TO INTOLERANCE TO GLUTEN. (It.) Nordio, S. (U. Genoa, Italy), G. Lamedica, L. Vignolo, A. Berio and G. Vignola. *Minerva Pediat.* 18(14):721-730, 1966.

Numerous case histories are presented. Secondary intolerance to lactose developed in an infant with transitory fat intolerance and in another with chronic diarrhea and eczema due to allergy to casein. Three cases of congenital and 1 of transitory intolerance to disaccharides are reported; in 1, both parents had a history suggestive of a hereditary factor; the transitory case may have been due to late maturation of the maltase activity of the intestine. Intolerance to lactose in a set of premature twins was thought to have a genetic basis aggravated by superimposed prematurity. A case of lactose intolerance in a patient with *Giardia lamblia* infestation was believed due to direct harmful effect of the parasite on intestinal saccharidase activity. In 2 other cases of lactose intolerance, 1 in a patient with congenital hypoplasia of the renal tubules and the other in a patient with primary hyperparathyroidism, the authors suggest that the absorption defect may be due to the hyperactivity of the parathyroid hormone or associated with malabsorption of calcium. A final case displayed an ill-defined intolerance to carbohydrates, with malabsorption of glucose, marked decrease in intestinal maltase activity, and hypergalactosemia with galactosuria and elimination of galactose in the feces after oral dose of the sugar. The authors suggest only that the diarrhea was due to an ill-defined disturbance of organic transport of galactose and glucose and to interference between the two at a level of the intestine where they are in competition with each other.

334 FOLIC-ACID DEFICIENCY IN ELDERLY PATIENTS ADMITTED TO HOSPITAL. (E.) Hurdle, A. D. F. (St. Thomas Hosp. Med. Sch., London) and T. C. P. Williams. *Brit. Med. J.* 2(5507):202-205, 1966.

An unselected group of 72 patients (46 females and 26 males, over 70 years in age) in hospital with a wide variety of diseases, excepting cirrhosis of the liver, were given a battery of tests on admission, including (among others) hemoglobin conc., WBC counts, serum folate conc., serum vitamin B₁₂ levels, neutrophil lobe counts, and folic acid absorption. Serum folate was less than 5 µg/ml in 28 patients. Only 12 of these were anemic with no more than 3 having hemoglobin of less than 10 g%. Included among the 12 anemic patients were 2 with megaloblastic marrow, 5 with iron deficiency, 1 with malignancy and 2 with uremia. Serum vitamin B₁₂ varied between 120 and 850 µg/ml with a mean figure of 374 µg/ml; 4 patients only had values between 120 and 140 µg/ml in all of whom the bone marrow was normoblastic. No correlation was found between folic acid deficiency and the presence of hypersegmented neutrophils. In tests of folic acid absorption no difference was found between patients with normal and those with low serum levels of folate. The results strongly suggest that nutritional deficiency is the primary factor in low serum levels in these individuals.

335 LACK OF GAMMA A-IMMUNOGLOBULIN IN SERUM OF PATIENTS WITH STEATORRHOEA. (E.) Crabbé, P. A. (U. Louvain Belgium) and J. F. Heremans. *Gut* 7(2): 119-127, 1966.

Three patients were reported on, all having steatorrhea in common and the absence or decreased α -immunoglobulin in the serum. Jejunal biopsy specimens were collected and showed a flat mucosa and atrophy of the villi with increased infiltration with lymphocytes, plasma cells and eosinophils in the lamina propria. Electrophoresis of serum proteins was carried out by Wieme's technic. Immuno-electrophoresis was performed using multivalent horse antiserum directed against human serum and specific rabbit antisera directed against each of the 3 human immunoglobulins. Sera immunoglobulins were determined by single radial immunodiffusion in agar-gel. Immunohistochemical studies of mucosa by specific antisera labeled with fluorescein isothiocyanate were carried out by the method of Crabbé *et al.*, 1965. Two patients were found to have normal γ -globulins. The third was hypogammaglobulinemic. Jejunal mucosa studies of the third patient showed no plasma cells with γ A and γ M-immunoglobulins in the lamina propria. The other two showed a reversal in the ratio of γ A cells to γ M-cells. It is suggested that patients suffering from idiopathic steatorrhea be studied for the presence of γ A-immunoglobulin in the serum.

- 10336 DISACCHARIDASE ACTIVITY OF THE DUODENAL MUCOSA IN INTOLERANCE TO GLUTEN, FIBROCYSTIC DISEASE OF THE PANCREAS AND MALNUTRITION. (It.) Berio, A. (Genoa, Italy), G. M. Lamedica, L. Vignolo, G. Vignola and S. Nordio. *Minerva Pediat.* 18(14):695, 1966.

In studies on 12 cases of celiac disease, a statistically significant decrease in all the disaccharidases (maltase, saccharase, isomaltase, and lactase) of the duodenal mucosa was found. The decrease in lactase was proportionally greater than that of the others, and after diet therapy lactase increased more slowly than the others. There was no correlation between the lactase level and the degree of inclusion of superficial cells within the upper layer of the crypts seen in duodenal biopsies. In 2 of 3 cases of fibrocystic disease of the pancreas, and in 1 of 3 cases of malnutrition, the disaccharidases, especially lactase, were also diminished. The authors conclude that decrease in disaccharidase activity, especially that of lactase, occurs in celiac disease, but that the phenomenon, although characteristic especially in conjunction with flattening of the intestinal mucosa, is not specific for the disease. Some correlation, albeit not very satisfactory, was demonstrated between lactase activity and blood levels of lactose; no correlation was found in the case of the other disaccharidases and their sugars. The enzyme defect is considered to be limited to the upper intestine, the area of prevalence of the mucosal lesions of celiac disease and an area which could be associated with the pancreatic dysfunction of fibrocystic disease.

- 10337 APPEARANCES OF THE JEJUNAL MUCOSA IN ACUTE TROPICAL SPRUE IN SINGAPORE. (E.) England, N. W. J. (Brit. Military Hosp., Singapore) and W. O'Brien. *Gut* 7(2):128-139, 1966.

Jejunum biopsies were taken from 24 control patients (14 Europeans, 10 Asians) and 36 European tropical sprue patients. Specimens were fixed and carefully sectioned, orientation of the villi being preserved. Mucosa patterns were judged as: villi, villi and leaves, leaves, thickened leaves, convolutions, and flat pavement. Measurements of height and width of villi and estimates of intensity of cellular infiltration were made. Xylose excretion tests were made and fecal fats estimated. Of 14 normal Europeans, 13 had villi and leaf pattern, 1 had predominate leaf pattern; compared to 36 sprue patients, 5 with villi and leaves, 5 with leaves, 14 with thickened leaves, and 12 with convolution mucosa patterns. Normal Asians had predominately leaf patterns. Mucosal thickness and villus height decreased in the sprue patients. Mean daily fecal fat excretion was found to be highly correlated with severity of jejunal pattern; mean urinary xylose excretion was inversely correlated with mucosal pattern. In patients with leaf or thickened leaf pattern successful treatment with folic acid rapidly returned mucosal patterns to normal; in those with convoluted pattern or severe atrophy recovery was delayed. In the majority the mucosa had recovered in 12-18 mo.

- 10338 ANTIRACHITIC ACTIVITY OF THE SERA OF PATIENTS WITH TROPICAL SPRUE. (E.) Haddock, L. (U. Puerto Rico Sch. Med., San Juan) and M. del C. Vázquez. *J. Clin. Endocr.* 26(8):859-866, 1966.

Serum calcium conc. determined by the Clark-Collip modification of the Kramer-Tis-
 all method were measured in 56 untreated tropical sprue patients, in 43 treated
 sprue patients in remission, and in 87 controls. Treatment for 6 mo.-2 yr. was
 based on folic acid. The antirachitic activity of the serum was determined by rat
 bioassay in 26 untreated sprue patients, 20 patients in remission and in 19 controls.
 Daily doses of 100,000 D₂/8 days were given to 2 controls, 3 untreated patients and
 1 patient in remission. Tropical sprue was diagnosed by clinical symptoms, macro-
 cytic hyperchromic anemia, megaloblastic bone marrow, D-xylose vitamin A and fat
 malabsorption with no other detectable causes. Serum vitamin D conc. in controls
 averaged 2.1 U/ml; in the untreated group, 1.2 U/ml; for the treated group, 2.2
 U/ml. All of the sprue patients having normal serum D conc. also had normal serum
 Ca levels. The av. serum Ca conc. for the controls was 9.8 mg/100 ml; for untreated
 patients, 8.8 mg/100 ml; for the treated group, 10 mg/100 ml. In sprue patients
 given D₂ daily, serum conc. decreased more rapidly than in controls given comparable
 doses. Serum vitamin D was markedly increased in sprue patients treated with folic
 acid from 21 days to 2 yr. It is concluded that the data suggest that there is a
 defect in the gastro-intestinal absorption of vitamin D in some hypocalcemic sub-
 jects with tropical sprue which appears to be corrected by folic acid therapy.

0339 NEOMYCIN-INDUCED STEATORRHEA. A PRELIMINARY REPORT ON THE IN VIVO HYDROL-
 YSIS OF A LONG-CHAIN UNSATURATED FAT. (E.) Rogers, A. I. (VA Hosp.,
 Coral Gables, Fla.), D. A. Vloedman, E. C. Bloom and M. H. Kalser.
J.A.M.A. 197(3):185-190, 1966.

Two volunteer male subjects were studied in 4 consecutive periods (14 days/period
 for one, 30 days/period for the other): (1) preneomycin, (2) neomycin (as the
 sulfate, 4 and 8 g/day), (3) neomycin and gluten-free diet, and (4) postneomycin.
 Neomycin intake was stopped 12 hr. before all analyses. Chemical data (intake and
 stool), bioptic specimens (jejunal at ligament of Treitz) and data on hydrolysis of
 fat in fluid aspirated from the jejunum were obtained at least once and sometimes
 twice in each period. Xylose tolerance tests and 96-hr quantitative stool analyses
 were done. Bioptic specimens were fixed, finally sectioned and stained (hematoxylin
 and eosin). During the neomycin period less than normal amounts of triglycerides
 were hydrolyzed within the intestinal lumen. No significant changes were noted
 when gluten was restricted while neomycin intake continued. In the postneomycin
 period the free fatty acids remained in reduced conc. The major histologic changes
 after 2 wk. of neomycin intake, were: (1) decrease in villus height with a tendency
 to clubbing of villi, (2) increase in round-cell infiltration and edema, (3) re-
 duction in height of epithelial cells at tips of villi, (4) some vacuolization of
 epithelial cytoplasm, (5) presence of active phagocytes in the region of basement
 membrane of villi. Chemical findings were: (1) Increase in stool fat during the
 neomycin periods, as compared to the preneomycin period, averaged 8.6 g/day in the
 8 g neomycin period and 17.6 g/day in the 4 g neomycin period. Stool wet wt. increase
 during the neomycin periods. Serum carotene levels fell an av. of 77.7 IU in the
 neomycin periods. Blood levels of D-xylose dropped a max. of 25 mg/100 ml in
 patient 1 and 50.8 mg/100 ml in patient 2 who had low urine levels of D-xylose be-
 fore neomycin admin.; patient 1 had striking decreases in urinary output of D-xylose
 during neomycin admin. Dietary gluten restriction (period 3) resulted in a signifi-
 cant decrease in stool fat content in patient 2 from 23 g/day to 14 g/day and in
 patient 1 from 20.5 g/day to 17.5 g/day. Patient 1 had a rise in blood level of
 carotene from 157 to 175 IU. No such rise occurred in patient 2 until neomycin was
 discontinued when carotene blood level rose from 50 to 116 IU.

0340 RADIATION-INDUCED PROTEIN LOSS INTO THE GASTROINTESTINAL TRACT. (E.)
 Vatisas, S. (Hammersmith Hosp., London) and S. Hornsey. Brit. J. Radiol.
 39(463):547-550, 1966.

The dose effect relationship for the leakage of molecules the size of plasma pro-
 teins into the small intestine after irradiation was studied by inoculating ¹³¹I-
 labeled polyvinylpyrrolidone (PVP) into the tail veins of mice and measuring the
 gamma-ray activity of whole mice, their feces and urine every 24 hr. after single-
 dose whole body X- or neutron irradiation of 380-1130 rads. Activity in the feces
 of unirradiated controls was 4% of total activity in the first 24 hr., and fell to

0 by day 3 and 4. Similar results were obtained from mice irradiated with either X-rays or cyclotron neutrons until, on days 3 or 4, the fecal activity rose sharply and remained high for about 5 days, with the time of increase being independent of dose. Dose effect curves obtained by plotting radiation dose against the per cent loss of the inoculated activity showed that (after an initial dose of 150-250 rads of X-rays or 30-50 rads of neutrons) the leakage of PVP increased linearly with dose. When the X-irradiation was given in 2 doses separated by 2-24 hr., the leakage was less for the total amount of radiation and was independent of the time interval between doses, but this sparing effect (160 rads at the 20% loss level) was much less than that which has been observed for morphologic damage to the intestine. The authors review the literature on protein-leakage and intestinal damage following irradiation and suggest that the relationship between the two effects is not close.

- 10341 DISACCHARIDASE ACTIVITIES OF DUODENAL MUCOSA IN CHILDREN. NORMAL SUBJECTS, CELIAC DISEASE, MALNUTRITION, CYSTIC FIBROSIS OF PANCREAS, OTHER CHRONIC ENTEROPATHIES. (E.) Nordio, S. (U. Genoa, Italy.), G. M. Lamedica, A. Berio and L. Vignola. Ann. Paediat. (Basel) 206(4):287-312, 1966. Duodenal mucosa specimens were obtained from 11 normal children (6 mo.-9 yr.), 12 children with celiac disease (9 mo.-4 yr.), 3 children (7-28 mo.) with serious malnutrition, 3 children (6 mo.-2 yr.) with cystic fibrosis of the pancreas and 4 other cases of chronic enteropathies; disaccharidase activities (maltase, sucrase, isomaltase, and lactase) were determined according to the method of Auricchio et al. (Enzym. Biol. Clin. 3:193, 1963). Great variability was found in all groups. It was concluded that in the pathological conditions studied, duodenal disaccharidase activities were generally decreased in comparison with normal subjects, both with and without disaccharide intolerance. Acquired factors seemed to be more important than genetic factors in producing these changes. Lactase activity appeared to be particularly sensitive. The clearest differences were seen in children suffering with the celiac syndrome.

- 10345 ORAL SUGAR LOADING TEST IN INTOLERANCE TO SUCROSE AND ISOMALTOSE. (Fr.) Lardinois, R. (Stanford Med. Ctr., Palo Alto, Cal.). Acta Paediat. Belg. 20(3):187-204, 1966.
- 10346 SOME OBSERVATIONS ON SUCROSE AND ISOMALTOSE INTOLERANCE. (Fr.) Lardinois, R. (Stanford Med. Ctr., Palo Alto, Cal.). Acta Paediat. Belg. 20(3):205-223, 1966.
- 10347 PROTEIN-LOSING GASTROENTEROPATHY. (E.)(Rev.) Gordon, R. S., Jr., T. Waldmann and L. Laster. DM 9:1-32, 1966.

- 0348 SURFACE MICROSCOPY OF THE LARGE BOWEL. (E.) Fabbrini, A. (U. Rome), A. Torsoli, A. Alessandrini, L. Onori, V. Greco, C. Casale, P. Arullani and M. Re. Experientia 22(6):408-410, 1966.

The surface examination of fresh or 10% formalin-fixed specimens of human colonic mucosa under relatively low powers revealed characteristics of normal and pathological states which may be of diagnostic value. A total of 59 bioptic samples were studied; these were obtained from 42 subjects of both sexes of whom 10 were free of digestive troubles, and 32 showed signs of various colonic disorders. The normal mucosae presented 2 distinct features: (1) a flat surface on which openings of mucous glands appeared round (10-30 μ diameter) or as thin clefts, spaced 110-250 μ apart, and (2) papillary-like folds uniformly spaced with a diameter of 100 μ . The opening of the mucous gland could be seen at the top of each fold. The papillary pattern may arise from activity of the muscularis mucosae. The following are some mucosal characteristics observed in disease: Mucous diarrhea presented (1) a wavy appearance of the mucosa due to small, translucent, closely associated areas corresponding to the goblet cells, and (2) irregular shape of gland openings which were much enlarged (up to 80-100 μ). A case of ulcerative colitis showed (3) wide depressed areas with surface roughness and a case of colonic carcinoma showed (4) a grossly alveolar aspect with depressions and large connecting folds; the depressions seemed to correspond with irregular and enlarged openings of glands. These preliminary data suggest that surface microscopy may be of value in the study of the colon. It is also possible that surface microscopy will aid in comparing histologic and radiologic pictures.

- 0349 THE MANAGEMENT OF ENDOMETRIOSIS INVOLVING THE BOWEL. (E.) Gray, L. A. (U. Louisville Sch. Med., Ky.). Clin. Obstet. Gynec. 9(2):309-330, 1966.

Of 20 patients with endometriosis treated by resection of the full thickness of the large intestine wall, 17 currently continue to present excellent results. In addition to large intestine resection, conservative resection of endometrial growths from the ovaries, pelvic peritoneum and uterosacral ligaments was performed in 4 patients, hysterectomy with retention of one or both ovaries in 3 patients and excision of the uterus and both tubes and ovaries in 13 because of extensive ovarian endometriosis and myomas of the uterus. In 17 patients, preoperative preparation of the large intestine included admin. of succinylsulfathiazole (2 patients) for 5 days and phthalylsulfathiazole and neomycin for 1 day to 5 patients. In all 20 patients, antibiotics were admin. postoperatively and nasogastric suction was used in 8 patients. Excision of endometriosis involving the large intestine was completely accomplished in 23 of 50 patients without entering the lumen of the large intestine. In the remainder, residual or moderate endometriosis remained which usually responded to oophorectomy and estrogenic therapy.

- 0350 SARCOIDOSIS WITH RECURRENT THROMBOPHLEBITIS AND IDIOPATHIC STEATORRHOEA. (E.) Smith, B. D. O. (Battle Hosp., Reading, England). Proc. Roy. Soc. Med. 59(6):569-570, 1966.

Eight mo. after onset of symptoms, a 31-yr.-old woman with clinical and laboratory manifestations of sarcoidosis developed pain and tenderness suggestive of incipient thrombophlebitis behind the right knee concurrently with retinal periphlebitis with partial central retinal vein thrombosis. In addition, she had a malabsorption syndrome with gross villous atrophy consistent with idiopathic steatorrhea by jejunal biopsy. Treatment with steroids, anticoagulants, and gluten-free diet with vitamin B₁₂ and folate produced an excellent response. Eighteen mo. later she had a deep venous thrombosis of the right leg coincident with increased sarcoid activity; improvement followed resumption of steroid and anticoagulant therapy.

- 0351 COLON MUCOSA RESPONSE TO INJURY. I. MORPHOLOGICAL STUDY. (E.) Melnyk, C. S. (U. Chicago, Ill.), R. E. Braucher and J. B. Kirsner. Gastroenterology 51(1):43-49, 1966.

A total of 60 lesions of the dog colon (30 burns and 30 biopsy wounds) were studied

at 1-21 days following their formation in the colonic mucosa of 10 healthy dogs weighing 10-20 kg. Both types of lesions were as standardized as possible, biopsy lesions on one side of the colon and burns on the other side; the lesions included varying amounts of muscularis mucosae. The procedures were repeated at 1-7-day intervals so that each dog had 4-8 lesions of each type of varying age. The distal colon was excised under anesthesia, split longitudinally, the lesions individually removed, together with some surrounding normal tissue, bisected, fixed and prepared for the optical microscope. Inflammatory and regenerative responses followed a dynamic and continuous sequence in both types of lesions with a great deal of similarity. In the early phase in the burns the wounds appeared as erythematous mounds with an irregular surface. Histologically these areas showed epithelial necrosis with some tissue separation; denuded areas had a covering of fibrin exudate containing inflammatory cells. Edema and extravasated red blood cells were noted in the lamina propria and submucosa. In the center of the lesion the muscularis mucosae had undergone damage, sometimes severe. Short borders of undifferentiated cuboidal cells were seen at the edges of the wound in 24 hr. Prior to this a squamous layer was seen. This differentiates into the cuboidal which, in turn, becomes columnar. The biopsy lesions have less edema and erythema. Although the muscularis mucosa had been removed in these specimens a base of a dense mixture of inflammatory cells and prominent vascular channels comes to underlie the developing epithelium. In the late stage there is a reduction in edema and hemorrhage and an increase in vascularity with organization of the base. A continuing series of regenerative processes ensue until at 3 wk. the gross lesions of both types are difficult to recognize. Microscopically the lesions were almost covered by an irregular, regenerated glandular epithelium of variable height and configuration; the lamina propria was hypercellular and broadened. The muscularis mucosa was replaced by connective tissue.

- 10352 COLON MUCOSA RESPONSE TO INJURY. II. HISTOCHEMICAL STUDY. (E.) Melnyk, C. S. (U. Chicago, Ill.), R. E. Braucher and J. B. Kirsner. *Gastroenterology* 51(1):50-58, 1966.

Sixty lesions of the colonic mucosa (30 burns and 30 biopsies) were studied histochemically in 10 dogs for the return of enzymatic activity in the regenerated mucosa at 1 to 7, 10, 14, 15 and 21 days following the production of the lesions. Adequate controls for each enzyme reaction were prepared by (1) incubating duplicate slides with and without substrate, (2) processing the normal colonic mucosa removed initial in creating the biopsy lesions, (3) processing multiple lesions simultaneously in groups for all enzymes, (4) evaluating the normal mucosa surrounding the lesion and the regenerating tissue in each section. In all, 16 enzymes were investigated including 8 separate dehydrogenases, 2 diaphorases, β -glucuronidase, acid and alkaline phosphatases, 5-nucleotidase, monoamine oxidase, and leucine aminopeptidase. Six other staining reactions, such as the Feulgen stain (specific for DNA), were also applied to these tissues. Enzymatic and other histochemical reactions were similar in the regenerating colonic mucosa following excision and heat injury; in these regenerating tissues the reactions were very nearly of the same magnitude as in the normal mucosa. Fat vacuoles were present in the leading edge of the regenerating epithelial layer in both types of injury. The study suggests that colonic mucosa may respond to various forms of extrinsic injury in a uniform manner.

- 10353 PRESSURE VARIATIONS IN THE RECTUM AND ILEUM DURING EXPERIMENTALLY INDUCED URGENCY OF DEFECATION. (E.) Bárány, F. (St. Erik's Hosp., Stockholm, Sweden). *Acta Med. Scand.* 179(Suppl. 445):455-461, 1966.

The rectums of 14 healthy controls and 32 patients with various gastrointestinal disorders were subjected to gradual distention by means of a water-filled balloon. Rectal motility was recorded from the balloon, and ileal motility with an endoradiosonde. A sudden contraction of the rectum with simultaneous onset of urgency and a burst of pressure waves from the ileum was the normal response; the rectum then became adapted within 2 min. Distention elicited a recto-ileal reflex except in 5 of 7 patients who had undergone truncal vagotomy and in 4 patients with resection of the upper rectum. Adaptation of the rectum to distention was absent in the 4 patients with rectal resection and in all 11 patients with functional diarrhea.

LARGE INTESTINE

The latter group, however, showed an almost tonic contraction of the rectum with persistent urgency and recto-ileal reflex; whereas the resected group exhibited a series of rhythmic contractions and relaxations, with much better toleration of urgency. Adaptation was slower than normal in vagotomized patients. Four constipated patients, 2 with partial resection of the colon, and 3 of 4 patients with gastroenterostomy without vagotomy exhibited normal responses.

354 MALIGNANT LYMPHOMA OF THE COLON. A STUDY OF 69 CASES. (E.) Wychulis, A. R. (Mayo Clinic, Rochester, Minn.), O. H. Beahrs and L. B. Woolner. *Arch. Surg. (Chicago)* 93(3):215-225, 1966.

Over a period of 57 yr., 69 patients had histologically proven malignant lymphoma of the colon at the Mayo Clinic, of whom 19 had another lymphomatous lesion in an extracolonic location (Group 2). Resections were done in 47 of the patients in Group 1 (40 of these were curative resections), whereas treatment for Group 2 varied, complicated by extracolonic lymphoma. Excluding postoperative deaths, a 5-yr. survival rate of 66.7% and a 10-yr. survival rate of 50% followed curative resections. In the entire series, male to female ratio was 2:1 and the duration of symptoms was about 6 mo. (abdominal pain, marked wt. loss and a change in bowel habits). Of those with malignant lymphoma in the colon only (Group 1), the cecum was the site of the lesion in 26, the lesion extending directly into the terminal portion of the ileum in 15. The main histologic classifications in this group were 10 mixed cell types, 16 reticulum cell sarcomas and 11 lymphocytic lymphosarcomas. In Group 2, these classifications contained 3, 6 and 5, resp. Prognoses were influenced negatively by involvement of either regional nodes or adjacent structures, or if the tumor extended beyond the colon. Postoperative irradiation was used in most cases.

355 PREVENTION OF INFECTION IN COLON SURGERY. (E.) Altemeier, W. A. (U. Cincinnati, Ohio), R. P. Hummel and E. O. Hill. *Arch. Surg. (Chicago)* 93(2):226-235, 1966.

In a series of 115 colon operations observed, 10 wound infections occurred (8.7%) which showed a direct correlation between the emergence of *Staphylococcus aureus* (phage type UC-18) in the stool and the development of wound infection by the same organism. This was noted 50% of the time. The postoperative admin. of penicillin and broad spectrum antibiotics (i.v. for 3 days) seemed to be the best prophylactic antibiotic combination against infectious complications following colon operations. Those patients who received only neomycin sulfate and phthalylsulfathiazole preoperatively had the highest incidence of wound infections, and approx. 50% of these patients developed *S. aureus* in their stool cultures. Those patients who also received prophylactic postoperative antibiotics had the highest incidence of staphylococcal enterocolitis. Advanced age, extreme obesity, remote foci of infection, prolonged preoperative hospitalization or operations are factors which seem to increase the incidence of wound infection. The authors feel that the contamination comes from an endogenous source.

356 MESODERMAL CHANGES IN ADENOMATOUS POLYPS OF THE LARGE INTESTINE. (E.) Chapman, I. (City Hosp. Ctr., Elmhurst, N. Y.). *Arch. Path. (Chicago)* 82(2):151-155, 1966.

Autopsy supplied 82 and surgery furnished 12 polyps, varying from a just visible size of flat verrucous-like excrescences to stalked bodies 3 mm in greatest dimension. Tissues were fixed, embedded and sectioned at 6 μ . Sections were stained in a number of different ways to show various extracellular structures and substances as well as cellular detail. Coincident with epithelial hyperplasia and structural changes in the epithelium were alterations of a consistent pattern occurring in the muscularis mucosae, the first being a widening of the muscular layer, the second separation of the inner circular layer and the outer longitudinal layer of muscle. Many of the lymphatic and small blood vessels were dilated with an associated mild inflammatory infiltrate primarily lymphocytes but with some monocytes, neutrophils and acidophils. The lamina propria contained an increase of collagen and reticulin; in places the lamina propria was obliterated by encroachment of smooth muscle cells. In the larger polyps, the muscle layers of the mucosa contained more collagen and reticulin. The lamina propria had disappeared and the muscle fibers were adjacent

to the basement membrane of the epithelium. The submucosa contained an increased number of blood vessels. Nerve fibers and ganglia also seemed to increase. The altered submucosa and muscularis mucosae formed the stalk of the polyp. The altered epithelium was always associated with the altered muscularis. Occasionally a region of altered muscularis was overlaid with normal epithelium.

- 10357 HIRSCHSPRUNG'S DISEASE AND MONGOLISM. (E.) Graivier, L. (U. Pittsburgh Sch. Med., Pa.) and W. K. Sieber. Surgery 60(2):458-461, 1966.

During the 12-yr. period ending in 1963, 84 patients with histologically verified Hirschsprung's disease were admitted to the Children's Hospital of Pittsburgh. Three of these cases were associated with Mongolism, bringing to 19 the total number of reported cases. All 3 cases were very young infants. Case 1: 8-day-old Caucasian boy showed all the stigmata of Mongolism. Abdominal series revealed colonic distention and barium enemas confirmed Hirschsprung's disease. This patient died at the age of 1 yr. after corrective surgery. Case 2: 12-hr.-old Caucasian boy entered the hospital with a diagnosis of imperforate anus. A distal pullthrough with resection of the distal 9 cm of the large intestine was performed; histologic study revealed that the terminal 5 cm of the colon was aganglionic. At 3 wk. of age he was readmitted when Mongolian stigmata were noted. At the age of 14 yr. he was still living, apparently well, with full-blown characteristics of Mongolism. Case 3: 7-day-old Caucasian boy admitted because of vomiting and abdominal distention. All usual signs of Mongolism were present. Barium enema examination established diagnosis of Hirschsprung's disease of the short segment type. A sigmoid colostomy was performed. Histologic examination of specimens taken confirmed diagnosis of a ganglionic megacolon. It is suggested that this dual condition of Mongolism and Hirschsprung's disease is due to chromosomal abnormality.

- 10358 CURRENT APPROACH TO THE POLYP-CANCER CONTROVERSY. (E.) Castleman, B. (St. Joseph Mercy Hosp., Ann Arbor, Mich.) and H. Krickstein. Gastroenterology 51(1):108-112, 1966.

In recent years there has been a continuing argument with respect to the role of adenomatous polyps in the development of carcinoma. Many case reports of a polyp becoming malignant are invalid for 1 or more reasons: (1) The so-called polyp may actually be a papillary adenoma which is often premalignant. (2) The so-called polyp may be a polypoid carcinoma, a low-grade cancer which may develop a stalk because of inability to infiltrate. (3) The lesions are well-differentiated, stalkless adenocarcinomas, diagnosed as sessile polyps on the basis of misleading radiologic appearance. (4) Supposed metastasis from a polypoid lesion when an additional ulcerative carcinoma has not been ruled out as a primary source. (5) A carcinoma has arisen in an area involved by familial polyposis. There is no proof of any connection between familial polyposis and adenomatous polyps. Cytologic atypia are often confused with and considered diagnostic of carcinoma, when, in fact, there is no evidence of invasion or metastasis. No intermediate stages of adenomatous polyps and carcinoma have been found. The estimates of incidence of colonic polyps range from 10 to 50% of the adult population over the age of 30 yr. It is obvious from this that most adenomatous polyps must remain benign; if not, carcinoma of the colon would dwarf in number all other tumors. In a study of over 4000 patients, the same incidence of cancers occurred after 5 yr. in colons without polyps as in colons with polyps. A recent survey disclosed an estimated 4,300,000 adults in the U.S. with colonic polyps 1 cm in size or greater; if all these underwent colonic resection on the basis of the 5% mortality rate for this surgery, deaths from the operation would be approx. 10 times the total annual number of deaths from carcinoma of the colon. A review of 6000 polypoid lesions of varied histological classification showed that metastases were almost nonexistent.

- 10442 **ULCERATIVE PROCTITIS: COURSE AND PROGNOSIS.** (E.) Farmer, R. G. (Cleveland Clinic Found., Ohio) and C. H. Brown. Gastroenterology 51(2): 219-223, 1966.

Follow-up information for 51 of 52 ulcerative proctitis patients was obtained which showed 36 cases of recurrent rectal bleeding (of whom 31 were again asymptomatic), 3 cases of colitis extension to more proximal portions of the colon and 1 case of sigmoid carcinoma. These 52 patients were among 1258 patients with ulcerative colitis seen over a period of 13 yr. On admission, all reported rectal bleeding, 40 complained of diarrhea and 24 of abdominal cramping; in the majority, these continuous symptoms had existed for less than 6 mo. Forty-four patients were treated with sulfa preparations and 27 with steroids. Most of the patients were in the age range of 21-50 yr. Sigmoidoscopic findings and rectal mucosal biopsies were indistinguishable from ulcerative colitis, which suggests that ulcerative proctitis is a localized, milder form of the latter where in systemic complications, toxic episodes, the need for surgical treatment and the development of carcinoma are rare.

- 10443 **RECTAL PARIETOGRAPHY IN ULCERATIVE COLITIS.** (E.) Virtama, P. (Cent. U. Hosp., Abo, Finland). Acta Radiol. [Diagn.] (Stockholm) 4(3):344-348, 1966.

With the patient in the Trendelenberg position, the rectal wall was demonstrated radiologically by inj. 200-400 ml of O₂ into the presacral space through a teflon catheter and simultaneously filling the rectum with barium. The presacral space and the thickness of the rectal wall were measured at the level of the 3rd and 4th sacral vertebrae. The rectal wall was thickened in 12 clinically and rectoscopically diagnosed severe cases of ulcerative colitis as compared to 14 controls. Because the width of the presacral space does not necessarily correlate with thickness of the rectal wall, rectal paretography is recommended for assessing possibilities for surgical intervention in ulcerative colitis.

- 10444 **THE LIVER-COLITIS SYNDROME.** (Ger.) Kaiser, C. (Chur Canton Hosp., Switzerland). Gastroenterologia (Basel) 105(6):335-350, 1966.

Two women with ulcerative colitis and hepatic complications are presented. In 1 patient with simultaneous ulcerative colitis and cholelithiasis, cholecystectomy and right colectomy with ileotransversotomy resulted in complete regression of all symptoms. Cholangitis and obstructive jaundice developed about 2 yr. later when the patient became pregnant; improvement was seen upon diet therapy with prednisolone and chlortetracycline (Aureomycin). The symptoms began to recur 6 mo. later, however; 16 mo. later a complete picture of splenomegalic biliary cirrhosis, melena, portal hypertension and esophageal varices was seen. The varices disappeared after splenectomy with splenorenal shunt, but the liver condition was unchanged (incipient biliary cirrhosis with portal hypertension). The patient was in good condition 9 mo. postoperatively (4 yr. after colectomy), although symptoms of anicteric intrahepatic cholestasis persisted. The other patient (who had experienced a brief course of afebrile jaundice 3 yr. previously) developed ulcerative colitis following a normal pregnancy, but continued to deteriorate despite symptomatic therapy over the next 12 mo. Cholelithiasis was suspected, but no stones were seen at cholecystectomy 2 mo. later; the pathological findings were chronic cholecystitis and posthepatic liver changes, possibly precirrhotic. No hypertension was present. The patient was improved only briefly, then continued to deteriorate over the next 6 mo. Symptomatic therapy (not described) then caused significant improvement. Moderate hepatosplenomegaly persisted, although the liver histology was normal 6 mo. later; slight bilirubinemia was present and the only abnormal liver function tests were elevations of serum leucine aminopeptidase and alkaline phosphatase. The patient was treated again with salazopyrine (no details) 6 mo. later and responded well clinically. At the time of report the same liver function tests were abnormal, confirming the diagnosis of postnecrotic cirrhosis, although liver histology was inconclusive.

- 10458 RECTAL MUCOSAL BIOPSIES AS A DIAGNOSTIC AID IN CYSTIC FIBROSIS. (E.) Jabro, I. H. (U. Nebraska Sch. Med., Omaha) and G. E. Gibbs. J. Lancet 86(7):385-388, 1966.

A series of 59 rectal suction biopsies were taken, 30 from 27 patients (1 mo.-11 yr. old) without cystic fibrosis, and 29 from 24 patients (6 mo.-19 yr. old) with cystic fibrosis. The instrument used was the multipurpose tube with a 2.9-mm aperture and a sliding, circular knife. The tube was passed about 5 cm into the rectum. The bioptic specimens were fixed and embedded so that the sections were cut exactly perpendicular to the mucosal surface. Normal biopsies revealed the following characteristics: (1) narrow glands; (2) no gaping of the gland opening; (3) no cryptic dilatations; (4) moderate amount of mucus and (5) no distortion of the configuration of glands. Biopsies from cystic fibrosis patients showed the following: (1) wide glands; (2) gaping of the gland opening; (3) wide dilatation of mucous glands; (4) large amount of mucus; (5) distortion of the configuration of glands, and (6) prominent goblet cells. Evaluation of the biopsies by independent observers, unaware of the diagnosis, resulted in 16 correct diagnosis of cystic fibrosis, 6 doubtful, and 1 negative. In the normal control group, 22 were listed as negative, 5 questionable, and 1 positive for cystic fibrosis. It is believed that this technic which is convenient, painless, safe, and practical is a useful addition to the diagnosis of cystic fibrosis.

- 10459 THE FUNCTION OF THE HOMOTRANSPLANTED CANINE PANCREAS. (E.) De Jode, L. R. (Whipps Cross Hosp., Leytonstone, London) and J. M. Howard. Brit. J. Surg. 53(4):364-371, 1966.

A viable functional pancreaticoduodenal homotransplantation was carried out in 24 of 32 dogs. Twelve dogs underwent total pancreatectomy in order to investigate the effects of the transplant on blood sugar. Fasting blood-sugar levels and glucose tolerance curves were determined before and after pancreatectomy and transplantation. Exocrine secretion of the transplanted pancreas was studied by cannulation of the pancreatic duct, allowing secretions to be collected. Amylase conc. was measured by Winslow's method. The effects of secretin 1-1.5 U/kg i.v. on both vol. and bicarbonate conc. were determined. Dogs prepared with a Routley type pancreatic fistula were used as controls. Homotransplanted pancreas was capsule of restoring blood sugar to normal levels in pancreatectomized dogs and maintaining it until rejection (7 days) occurred. Oral glucose-tolerance curves in transplanted pancreatectomized dogs differed only slightly from controls; i.v. glucose-tolerance curves were almost identical to control. Basal secretion from the transplant was similar to control. A significant increase in vol. and bicarbonate after i.v. secretin inj. was observed. The levels were approx. 10% of control levels. The ranges of amylase activity in the resting state and following secretin were nearly identical. Differences in function between the control and transplant were attributed to exclusion of the tail of the pancreas in the transplant, trauma due to surgery, and denervation of the pancreas.

- 10460 HISTOPATHOLOGY OF AMINO ACID DEFICIENCIES. VIII. ELECTRON MICROSCOPY OF THE EXOCRINE PANCREAS CELLS OF LYSINE-DEFICIENT RATS. (E.) Scott, E. B. (U. South Dakota Sch. Med., Vermillion). Arch. Path. (Chicago) 82(2):119-128, 1966.

Forty-six young rats of both sexes were divided into 3 groups: Group 1, normal control was fed a purified diet consisting of 19 crystalline amino acids, vitamins, sucrose, cottonseed oil and minerals; Group 2 received the same diet except for total omission of lysine. The caloric value of the missing amino acid was made up by sucrose; Group 3 was pair-fed the complete diet in such amount that the daily consumption of each animal was equal to that of its deficient partner. Rats were kept in individual cages with free access to water; control and deficient rats fed ad libitum. Rats from each group were killed at 34-95 days. Pancreatic tissue was prepared for light and electron microscopy. The normal rats consumed a daily av. of 12.7 g of food and the deficient rats ate an av. of 3.9 g/day. Wt. of normal controls increased from an av. of 58 g to 254 g in 95 days, an increase of 338%.

CRINE PANCREAS

ing the same time the wt. of the pair-fed group increased from 63-84 g, a 33% increase. The deficient group lost 17% body wt. No important histologic or cytologic differences could be seen between the normal controls and the pair-fed rats. Changes in the exocrine pancreas of all deficient rats were the same regardless of sex or duration of experimental period. In the deficient rats acinar cells were smaller than normal, frequently separated by interstitial edema. Zymogen granules were reduced in number, and exhibited fragmentation of the bounding membrane. The acinar body was not seriously affected, and no significant changes were observed in the cell nuclei or ergastoplasm. Large clusters of lipid droplets were very conspicuous at the base of the cells. Mitochondria were swollen and deformed, exhibiting displacement of cristae and degenerative changes resulting in myelin formation. These are the sum of the effects of lysine deficiency superimposed on the nonspecific effects of partial inanition.

- 61 THE SWEAT TEST IN CYSTIC FIBROSIS. A COMPARISON OF OVERNIGHT SWEAT COLLECTION VERSUS THE Pilocarpine Iontophoresis Method. (E.) Shwachman, H. (Harvard Sch. Med., Boston, Mass.) and A. Mahmoodian. J. Pediat. 69(2):285-287, 1966.

Comparative electrolyte levels in sweat collected by pilocarpine iontophoresis and non-stimulated overnight accumulation from 29 patients with cystic fibrosis and 47 controls with either pulmonary or gastrointestinal complaints are presented. The collection was accomplished by applying a weighed gauze pad to a cleaned area on the patient's back and removing for reweighing and analysis. The control patients showed some conc. of sweat electrolytes by both methods. The mean Na value was approx. 23 mEq/liter while the mean Cl value was approx. 25 mEq/liter. The pilocarpine iontophoresis stimulated more sweat. Patients with cystic fibrosis showed elevated electrolytes with those who slept in mist tents exhibiting the highest values. Slightly lower Na and Cl conc. were obtained by the overnight collection method. Less sweat was found in patients sleeping in mist tents. The mean Na value for cystic fibrosis patients in the mist tents was 98.2 mEq/liter for overnight collection and 115.2 mEq/liter for pilocarpine iontophoresis. The mean Cl values for these respective conditions were 105.8 mEq/liter and 127.8 mEq/liter. The mean Na and Cl values via overnight collection for the cystic fibrosis patients not in mist tents were 100.1 and 107.0 mEq/liter, resp., while, values obtained for the Na and Cl conc. by pilocarpine iontophoresis on the same patients were 102.1 and 117.7 mEq/liter, resp.

- 62 SELECTIVE PANCREATIC ANGIOGRAPHY. (E.) Boijesen, E. (U. Hosp., Lund, Sweden). Brit. J. Radiol. 39(463):481-487, 1966.
- Selective pancreatic angiography was performed percutaneously via the left celiac artery in 21 patients, 7 of whom had tumors of the pancreas or of the gastroduodenal ligament. A comparison was made of inj. into the gastroduodenal artery (7 patients), the common hepatic artery close to the gastroduodenal artery (7 patients), and the common hepatic artery 1-4 cm from the gastroduodenal artery (7 patients). The best demonstration of the pancreatic arteries was obtained with the tip of the catheter in the gastroduodenal artery, one reason being that local spasm of the artery occluded it around the catheter tip. With the tip near the origin, however, visualization of the complete arterial supply of the head of the pancreas and, less consistently, of the main arteries of the body and tail was obtained. Distal common hepatic artery inj. gives additional information on the arterial supply of the liver; also, contrast medium may reflux into the splenic artery. In all 7 patients with tumors, the diagnosis, location, and approx. size were established. The superselective technic gives superior vascular detail when compared with celiac-superior mesenteric angiograms, and seems to be the method of choice when the latter method does not give clear-cut results.

- 63 INCIDENCE AND SEVERITY OF NUTRITIONAL DEFICIENCY STATES IN CHRONIC EXOCRINE PANCREATIC INSUFFICIENCY: COMPARISON WITH NONTROPICAL SPRUE. (E.) Evans, W. B. (Mayo Clinic and Mayo Found., Rochester, Minn.) and E. E. Wollaeger. Am. J. Dig. Dis. 11(8):594-606, 1966.
- The incidence of various nutritional deficiency symptoms and signs in 90 patients

EXOCRINE PANCREAS

with untreated or inadequately treated exocrine pancreatic insufficiency due to chronic relapsing pancreatitis (60), pancreatic atrophy (7), inoperable pancreatic carcinoma (9), or sequelae of Whipple's operation (14), compared to symptoms in a previously reported series of 124 cases of nontropical sprue (described by Green and Wollarger), was: diarrhea or steatorrhea or both in 92% and 90%, resp.; wt. loss in 90% and 88%, resp.; increased appetite and food intake in 69% and 15%, resp.; severe abdominal pain in 64% and 0, resp.; nausea and vomiting in 46% and 30%, resp.; diabetes mellitus in 36% and 2%, resp.; edema or ascites or both in 12% and 50%, resp.; paresthesias in 10% and 25%, resp.; weakness in 7% and 95%, resp.; and purpura simplex in 4% and 0, resp. Symptoms seen only in patients with nontropical sprue were tetany (40%), hemorrhage (23%), anorexia (30%), nocturnal polyuria (19%) and bone pain (19%). The patients with exocrine pancreatic insufficiency also failed to show hemorrhage due to prothrombin deficiency, osteomalacia, severe anemia, or anemia due to iron or folic acid deficiency. Rectal passage of gross oil was seen in 57% of the patients with exocrine pancreatic insufficiency, but none of the patients with nontropical sprue had this symptom; this sign is regarded as helpful in the differential diagnosis of exocrine pancreatic insufficiency from other nutritional deficiency states.

- 75 THE ETIOPATHOGENESIS OF ACUTE AND CHRONIC RECURRENT PANCREATITIS. (Rus.)
Toskin, K. D. (Crimean Med. Inst., USSR). Khirurgia (Moskva) 42(5):68-73,
1966.

52 patients with acute pancreatitis on whom radiologic studies or gastroduodenal
activity were done within 1 wk. after onset of symptoms, signs of dyskinesia were
observed in 27: spastic contractions of the duodenum, antiperistaltic waves, and
stasis and pendulum-like progression of the barium meal. The role of elevated duo-
denal pressure in triggering attacks of acute and chronic recurrent pancreatitis
was explored in chronic experiments with sudden and gradual rises in pressure in
dogs with exteriorized duodenum. Abrupt rises in duodenal pressure produced
attacks of acute pancreatitis, and repeated, transient rises caused duodenal changes
characteristic of chronic recurrent pancreatitis. In the presence of duodenal
hypertension, stimulation of pancreatic secretion by pilocarpine accelerated the
development of severe pancreatitis. When duodenal pressure was raised moderately
gradually, no pathologic changes were observed in the pancreas, but biliary
calculi did appear.

- 76 FURTHER OBSERVATIONS ON CALCIFIED MEDULLARY BONE LESIONS IN CHRONIC
PANCREATITIS. (E.) Bank, S. (U. Cape Town, South Africa), I. N. Marks,
J. Farman and E. J. Immelman. Gastroenterology 51(2):224-230, 1966.

Case history is presented which provides further support for an association
between relapsing pancreatitis and intramedullary calcification in bones. This
37-yr.-old male patient had a 7-yr. history of recurrent pancreatitis and a 17-yr.
history of excessive alcohol intake. Two large fluctuating swellings were present
over both hips in the region of the femoral trochanters. In addition, the left
crural bursa was distended with fluid and the left shoulder joint was painful
and swollen. Skeletal radiographs showed that the lower end of the right femur had
regular calcification in the medulla, and periosteal reaction was evident on the
lateral and anterior aspects of the adjacent shaft. The left shaft showed possible
osteolucency at its distal end. A biopsy from each of these areas showed scattered
islands of necrotic fat cells on the left and on the right, large areas of necrotic
fat cells of which some were surrounded by calcified deposits. Inflammatory cells
were absent in both biopsies. Additional testing showed pancreatic function to be
grossly impaired, protein malnutrition and advanced liver cirrhosis.

- 77 RELATIONSHIP OF AZOTEMIA AND SURVIVAL IN BILE PANCREATITIS IN THE DOG.
(E.) Frey, C. F. (U. Michigan Med. Ctr., Ann Arbor) and G. L. Brody.
Arch. Surg. (Chicago) 93(2):295-300, 1966.

Although renal function as measured by blood urea nitrogen, creatinine and para-
aminohippuric acid clearances is impaired in fatal pancreatitis in dogs, no uniform
pathologic changes were noted in the kidneys. Swollen ischemic glomeruli similar
to those seen in humans with lower nephron nephrosis were present in about half
of the dogs. After inducing fatal pancreatitis (by a forceful retrograde inj. of
1 ml/kg of autologous bile into the main pancreatic duct which was then ligated),
administration of antibiotics increased the survival, but did not alter the degree of
azotemia; whereas, i.v. electrolyte replacement maintained renal function but did
not alter survival. Therefore, survival and maintenance of renal function in bile
pancreatitis in dogs was not equivalent. Sympathectomy and splanchnicectomy
advanced both survival and renal function to a lesser extent.

- 78 PANCREATITIS: A RETROSPECTIVE STUDY. (E.) Corlett, R. J. (Prince Henry's
Hosp., Melbourne, Australia), A. Sati and J. Hansky. Med. J. Aust.
2(2):54-59, 1966.

Over a period of 10 yr., 172 patients were admitted with a diagnosis of pancreatitis.
This diagnosis was confirmed in 141 cases: 98 with acute P and 43 with chronic P.
The following were the conditions most commonly found in association with acute P:
gallbladder disease, 43%; alcoholism, 34% and peptic ulcer, in 20% of the cases.
Twenty-two percent of these patients were considered obese. An elevation of leukocyte
count greater than 10,000/mm³ raised serum amylase and alkaline phosphatase levels

were the most significant laboratory findings in these cases. Treatment was surgical (with 7 deaths) for 42 cases and medical (with 8 deaths) for 41. Excess alcohol intake or gallbladder disease was present in 41 of the 43 cases of chronic P. Peptic ulceration was associated in 25% of these cases. Fecal fat levels and serum alkaline phosphatase levels both were increased in these patients. Steatorrhea was found in 20 cases and diabetes mellitus in 14. Treatment was medical for 23 cases (with 4 deaths) and surgical for 15 (with no deaths). No relationship was found between blood type and the incidence of P in this series. There was a slight predominance of male patients.

- 10479 THE MANAGEMENT OF CHRONIC RELAPSING PANCREATITIS. (E.) Warren, K. W. (Lahey Clinic Found., Boston, Mass.). Henry Ford Hosp. Med. Bull. 14(2):143-156, 1966.

Based on experience with 529 patients who underwent 543 operative procedures for chronic relapsing pancreatitis (P), direct ductal decompression or pancreatic resection to relieve the intrapancreatic obstruction is advocated. The operation must be tailored to each patient, however, based upon the phase of the disease and the specific pathologic changes found at laparotomy. Cysts are usually drained internally and abscesses externally. Transduodenal sphincterotomy is performed only in combination with probing, retrograde dilatation, and intubation (or incision) of one or both pancreatic ducts. When there is more than one point of obstruction, the duct of Wirsung is incised; occasionally a pancreatic duct gastrostomy is constructed, using a long limb T tube, or a permanent anastomosis between the duct and a segment of the gastrointestinal tract is made. Distal pancreatectomy is the method of choice when pathology is confined to this segment. Pancreatoduodenectomy (combined with subtotal gastrectomy) is justified in cases with long-standing disease, many points of obstruction, and failure of lesser operations. Total pancreatectomy is reserved for patients with destruction of the entire pancreas and pancreatolithiasis involving the whole ductal system. Pancreatography is used as a diagnostic aid only in unusual cases, most operative procedures being selected at laparotomy by direct observation of the pathology.

- 10480 KININASE ACTIVITY IN EXPERIMENTAL PANCREATITIS. (E.) Nugent, F. W. (Lahey Clinic Found., Boston, Mass.), W. A. Atendido, M. B. Bulan and A. J. MacDonald. Nature (London) 211(5045):207-208, 1966.

Eight mongrel dogs were used in the study of plasma kininase levels after production of pancreatitis by forceful inj. of 10 ml of dog bile into the major pancreatic duct. Venous blood was collected at 0, 2, 4, and 6 hr.; 2 dogs also supplied 8-hr. samples. For each test 5 ml of blood was centrifuged and 0.5 ml of the plasma was diluted to 20 ml with buffered saline; 5 ml of this diluted plasma was incubated at 37° C with an equal vol. of a standard soln. containing 0.05 µg of bradykinin. A rat uterus bioassay system unresponsive to histamine, serotonin, and catecholamine was used to test vasoactivity of the incubated dog plasma preparation at 5-min. intervals until no activity was detected. Plasma kininase levels increased during the first 8 hr. of pancreatitis in all dogs. The time for total inactivation of 0.05 µg of bradykinin decreased from a mean control time of 39 min. to a mean of 23 min. in the 6 hr. pancreatitis specimens. No change in the level of plasma kininase was detected during sham pancreatitis.

GENERAL

- 10501 A SENSITIVE METHOD FOR SERUM ORNITHINE CARBAMYLTRANSFERASE DETERMINATION. (E.) Ceriotti, G. (Tumor Stud. Ctr., Busto Arsizio, Italy) and A. Gazzaniga. Clin. Chim. Acta 14(1):57-62, 1966.

An accurate, rapid colorimetric method for the measurement of serum ornithine carbamyltransferase (OCT) is presented, based on citrulline determination by the diacetylmonoxime-phenazone reaction. The citrulline is formed by serum OCT from ornithine and lithium carbamylphosphate. Only 0.2 ml of serum and 1 hr. for incubation at 37° are required for the test. However, to find the amount of citrulline originally present in the serum (basal citrulline) an additional 0.5 ml of serum is needed. The colorimetric readings are taken against properly prepared blanks. Serum urea is removed from the reaction mixture by the addition of urease during the course of the procedure. The absorbance of the diacetylmonoxime-phenazone reaction has the same molar coefficient for both urea and citrulline. Calculations involved in the test are simple. The mean citrulline production in serum of normal subjects has been determined as 48 μ mole/ml/hr. In viral hepatitis rates up to 3230 n-moles/ml/hr. have been recorded.

- 10502 STUDIES OF CELLULAR TOXICITY OF UNCONJUGATED BILIRUBIN IN KERNICTERIC BRAIN. (E.) Schenker, S. (U. Cincinnati Sch. Med., Ohio), D. W. McCandless and P. E. Zollman. J. Clin. Invest. 45(7):1213-1220, 1966.

Diminished levels of adenosine triphosphate (ATP) and hyperbilirubinemia occurred in the cerebellum of two-week-old jaundiced Gunn rats (having a hereditary unconjugated hyperbilirubinemia) which were made kernicteric by daily s.c. inj. of 250 mg/kg of sulfisoxazole. On the av., the respiration of the kernicteric cerebellum was 19.3% lower than the controls, whereas whole brain O₂ consumption of the two were similar. The degree of hyperbilirubinemia in the cerebellum correlated with the severity of cerebellar signs which ranged from incoordination, ataxia, drowsiness, convulsions to death. The ATP levels were similar in both groups in the cerebral cortex and subcortical regions.

- 10503 THE KARYOGRAM OF THE HUMAN LIVER UNDER NORMAL AND PATHOLOGIC CONDITIONS. (Ger.) Altmann, H.-W. (U. Würzburg, Germany), K. Loeschke and K. Schenck. Virchows Arch. Path. Anat. 341(2):85-101, 1966.

Samples of hepatic parenchyma from prepubescent children contained only diploid nuclei. Tetraploid nuclei appeared for the first time in samples from children around age 13 and increased progressively in samples from subjects over 40. Cells with nuclei of more than tetraploid value were not seen in samples from children 15 yr. old or younger; were present in relatively small numbers (0.1-0.6%) in subjects under 40; then increased slowly to reach a max. (3.3%) about age 60, declining slowly thereafter. Although a very few binuclear cells were in evidence in all samples, an abrupt increase of their number (by approx. 20 times) was seen in samples from adolescents around 17, with the percentage incidence remaining fairly constant thereafter despite a considerable range of individual variation. In samples from patients with acute hepatitis, the distribution of nuclear types was highly irregular, due in part to the increased mitotic index. In these subjects, occurrence of a much larger number of polyploid nuclei than would be normal for the patient's age appeared to follow slowing down or exhaustion of the regenerative process. A similar increase of the incidence of polyploid cells was also seen in the presence of disturbance of the physiological cell-replacement mechanism in posthepatitis states and in patients with hepatic cirrhosis.

- 10504 STUDIES ON THE RESISTANCE OF LIVER TISSUE TO TEMPORARY ISCHEMIA. (Ger.) Eisenbach, J. (U. Frankfurt/M., Germany), H. H. Hirsch and J. Hartleib. Bruns Beitr. Klin. Chir. 212(3):328-335, 1966.

Eight groups of 3 mongrel dogs each were laparotomized under pentothal anesthesia and the blood supply to one liver lobe clamped for from 10-90 min. Biopsies were taken for histologic studies and a 300-800 mg portion of liver tissue immersed in liquid air within 10 seconds after removal. This tissue was later homogenized

ER AND BILIARY TRACT

used for ATP, ADP, and lactic acid determinations. Inorganic phosphorus (P) also determined. The dogs were relaparotomized 2-10 wk. later for follow-up studies. Ischemia of up to 25 min. duration produced no tissue damage. ATP and P values, which had dropped significantly immediately after the experiment, tended to be higher after 2 wk., approaching normal values at 10 wk. Lactic acid P increased sharply, but reverted to near normal at 10 wk. After ischemia of 5 min. duration some swelling and fatty degeneration of liver cells occurred and appeared to persist. Decrease of ATP and ADP was more pronounced immediately after experiment and while ATP returned to about normal values, as above, ADP levels were greatly increased after 2 wk. (even beyond the original levels), normalization actually occurring after 10 wk. Because of this high ADP accumulation the histologic changes mentioned in the 30-45-min. groups must be considered serious. Lactic acid and P values showed the patterns observed in the 10-25-min. ischemias. Histologic study after a 60-min. ischemia showed definite signs of parenchymal damage (focal necrosis) and later on, massive connective tissue infiltration and relative scarcity of parenchymal cells. An immediate and sharp drop in ATP and P values became even greater after 2 wk. Normal levels were not reached after 10 wk. but were slowly increasing. Lactic acid and P values were the same as before. Animals subjected to 90-min. liver ischemia did not survive beyond 24-48 hr.

- 05 RETROGRADE VENOUS CIRCULATION AND PORTACAVAL ANASTOMOSIS. (E.) Petrov, B. A. (Sklifosovskii Inst., Moscow) and L. L. Gugushvili. Surgery 60(2): 373-378, 1966.

Under certain conditions not too clear at the present time, when a portacaval shunt anastomosis exists, a retrograde flow of blood occurs in the hepatic veins. The passage of blood from the inferior vena cava was demonstrated by means of angiography in 14 dogs (4 of them with portal anastomosis). In 10 dogs a dye and a fat emulsion were inj. into the inferior vena cava. The passage of these substances into the hepatic veins as well as into their small branches was ascertained in tissue sections. Measurements of blood pressure in the inferior vena cava and hepatic veins prior to and after ligation of the portal vein showed that 10-20 min. after portal vein ligation the blood pressure in the inferior vena cava increased by 1.5-2 times. At the same time the blood pressure in the hepatic veins declined by 75%.

- 06 THE LIVER IN LIPIDOSIS. AN ELECTRON MICROSCOPIC AND HISTOCHEMICAL STUDY. (E.) Volk, B. W. (Jewish Chronic Dis. Hosp., Brooklyn, N. Y.) and B. J. Wallace. Am. J. Path. 49(2):203-226, 1966.

Liver biopsy specimens were procured from patients with several forms of lipidoses: (1) Niemann Pick Disease (NPD), (2) acid polysaccharidosis (AMP), (3) Gaucher's Disease (GD), and (4) Tay-Sachs Disease (TSD). The biopsy specimens were quickly divided into 4 parts, 1 each for optical and electron microscopy, 1 for biochemical and 1 for histochemical studies. A number of control specimens from individuals without any type of lipidosis were also processed. Acid phosphatase (AcPase) was demonstrated with beta glycerophosphate as substrate. Mucopolysaccharide was identified by a modification of the Hall staining technic. No peribiliary bodies were found in NPD but numerous large lipid bodies were scattered throughout the cytoplasm. The peribiliary bodies were also lacking in AMP but vacuole-like cytoplasmic inclusions containing AcPase were observed in hepatocytes. Gaucher bodies were found in both juvenile and infantile forms of GD. In the infantile form hepatocytes contained pale vesicles not observed in the older patients. In TSD, the membrane filled cytosomes in hepatic cells occasionally resembled the membranous cytoplasmic bodies found in neurons. These also exhibited AcPase activity. It is suggested that the storage material accumulates in hepatic peribiliary dense bodies resulting in the formation of altered lysosomes.

- 07 THE LIVER IN MURINE TRANSPLANTATION (RUNT) DISEASE. OBSERVATIONS OF THE ACUTE LESIONS BY LIGHT AND ELECTRON MICROSCOPY. (E.) Arakawa, K. (U. Toronto Banting Inst., Toronto, Canada), A.-M. Jézéquel, S. I. Macvie, R. Johnston, Z. M. Perz and J. W. Steiner. Am. J. Path. 49(2):257-299, 1966.

LIVER AND BILIARY TRACT

Strain C57Br/cdj adult mice were chosen as the donor and Connaught Strain (CS) inbred mice served as recipients within 24 hr. after birth. Suspensions (0.05-0.1 ml) of splenic donor cells were inj. i.v. or i.p. under aseptic conditions into recipients; 195 mice received allogenic cells i.v. and 99 mice i.p. The animals were killed serially 5-25 days after inj. and the liver examined grossly and by optical and electron microscopy. Liver lesions form a prominent part of the runtting syndrome. The main features of the lesions are: (1) a proliferation of mononuclear cells in portal tracts, (2) the appearance of a large number of plasma cells in spaces of Disse, (3) the persistence of hematopoiesis beyond day 11 of life, (4) a maturation arrest of hematopoietic cells, (5) focal subcapsular necrosis and (6) a fairly massive hepatomegaly, which may be due to hyperplasia of hepatocytes judged by the increase in hepatocyte DNA synthesis. The necrosis may result in part from the compression of parenchyma by Glisson's capsule. A precipitation of fibrin occurs in the spaces of Disse and platelet thrombi form in sinusoids.

- 10508 INJECTION STUDIES OF THE SPLENIC VASCULATURE IN PORTAL HYPERTENSION. (E.) Manenti, F. (Royal Free Hosp., London) and R. Williams. Gut 7(2):175-180, 1966.

Using either latex casts or radio-opaque barium-gelatin preparations of 12 spleens taken from patients with cirrhosis, it was seen that the total arterial and venous vol. increased in proportion to the size of the spleen, which was more than twice that of control spleens. Despite this proportional increase, the contribution of the arterial system to this increased vol. was considerably greater than that of the venous system because the number of small peripheral arterioles of approx. 100 μ diameter was increased. The mean terminal branching ratio for the latter was 13/2 in the cirrhotic patient's spleen as compared to 8/3 in the controls. In 50% of the cirrhosis cases, small arterial aneurysms were present, often deep in the hilum at the bifurcation of vessels. Arteriovenous shunts were not observed.

- 10509 TOXICITY OF IMMUNOSUPPRESSIVE AGENTS: EXPERIENCE WITH TRANSPLANTATION OF THE LIVER. (E.) Starzl, T. E. New Physician 15(7):175-179, 1966.

Although liver homotransplantation has been more successful in the laboratory than was the experimental work conducted on kidney homotransplantation, hepatic homotransplantation has not yet worked in the human. Extracorporeal perfusion of a cadaver to which coolant is added by means of a heat exchanger enables the removal of the liver without too much anoxia. Despite this, the homografts used have all had a relatively severe degree of ischemic injury. A significant problem occurs in the coagulation mechanism: during the transplantation an explosive increase in fibrinolytic activity occurs which is followed within a day or so by a rebound hypercoagulability. None of the livers in the human cases has had unequivocal evidence of rejection, even as long as 23 days after operation. Azathioprine has been the most successful agent for prevention of rejection. A series of dog orthotopic transplantations and auxiliary liver transplantations are also presented.

- 10510 COLD PRESERVATION OF EXCISED ASANGUINEOUS LIVERS. (E.) Van Wyk, J. (U. Kentucky Sch. Med., Lexington) and B. Eiseman. Gastroenterology 51(2):207-212, 1966.

When an excised pig liver is washed free of its contained blood with 8 liters of cold (4° C) heparinized Ringer's lactate soln. and then immediately cooled to 4° C, function can be maintained for 12 hr. Function is maintained for 6 hr. if the liver is placed in a 4° C refrigerator immediately following excision without rinsing. Prior to operation the animals had received 1 g of streptomycin and 1 million U of penicillin. Heparin (1 mg/pound) was admin. i.v. immediately before hepatectomy. Tests for functional integrity included bile production, ammonia clearance, sulfobromophthalein clearance, rate of perfusion and O₂ utilization. All the livers, which included 10 preserved by the slow cooling, unrinsed technic and 6 preserved by the rapid cooling, rinsed technic, were studied for 24 hr.

- 10511 THE EFFECT OF ACUTE HYPERAMMONIEMIA ON THE ELECTROENCEPHALOGRAM. (E.) Cohn, R. (U. S. Naval Hosp., Bethesda, Md.) and D. O. Castell. Dis. Colon Rectum 9(6):195-205, 1966.

LIVER AND BILIARY TRACT

With the exception of 1 case, acute hyperammonemia (produced by oral loading with 10 g of ammonium acetate in 60 ml of water) did not produce a major change in the electroencephalograms (EEG) of 19 patients with liver disease. The EEG during the period of peak arterial ammonia conc. was comparable to the EEG taken with the patient in a fasting state and an arterial ammonia range of 50-190 μ g%. The 1 exception was a patient whose EEG during the height of arterial ammonia (over 1,000 μ g% ammonia) showed an alpha frequency below 8 waves/second. Despite this distinction, change in the "raw EEG" pattern or in the frequency distribution was seen. All patients received 10 mg of prochlorperazine i.m. 30 min. before the test to prevent emesis. These findings support the concept that the ammonia which is immediately available to the brain from the blood is not the major determinant of gross changes in the EEG seen in patients with hepatic encephalopathy.

512 BIOMYCIN AND LEVOMYCETIN IN THE PROPHYLAXIS OF ALIMENTARY FATTY DYSTROPHY OF THE LIVER IN RATS. (Rus.) Gadzhiev, K. E. (Inst. Med., Daghestan, USSR) and I. A. Shamov. Biull. Eksp. Biol. Med. 61(6):42-46, 1966.

Chronic liver damage resembling the fatty atrophy resulting from human malnutrition can be produced in experimental animals by diets deficient in choline and prevented by feeding them certain antibiotics. In these experiments, 20- to 30-day-old rats were given a "cirrhotogenic" diet, supplemented or not by 25 mg/day of biomyacin (chlorotetracycline) or levomycetin (chloramphenicol); controls were admin. a completely adequate, unsupplemented diet. Histologic study of the livers of rats killed after 2, 6, 7, or 9 mo. showed that biomyacin prevented the fatty dystrophy of the liver produced by chronic choline deficiency. Chloramphenicol, on the other hand, actually aggravated the condition. These opposite effects of the 2 antibiotics are presumed to be due to differences in their effects on intestinal microorganisms responsible for the synthesis of essential vitamins.

513 INCREASED INCIDENCE OF SEVERE HYPERBILIRUBINEMIA AMONG NEWBORN CHINESE INFANTS WITH G-6-P D DEFICIENCY. (E.) Lu, T.-C. (Nat. Taiwan U. Coll. Med., Taipei), H. Wei and R. Q. Blackwell. Pediatrics 37(6):994-999, 1966.

The incidence of glucose-6-phosphate dehydrogenase (G-6-P D) deficiency in Chinese newborns under study was low, but deficient infants showed a tendency to develop severe and prolonged hyperbilirubinemia. A total of 1593 infants were surveyed for RBC G-6-P D deficiency by modification of the dye decolorization test of Motulsky and Campbell. Infants with Rh and ABO incompatibilities were not studied. The qualitative G-6-P D test of Zinkham *et al.* was made on infants shown to be G-6-P D deficient. The confirmed cases were tested daily for total serum bilirubin by the method of White *et al.* until the day of peak level was passed. Among 878 males tested, 26 (3%) were shown by both G-6-P D testing procedures to be deficient. One of 715 females was deficient by the screening procedure showing its failure to detect intermediate reactors among female infants. The mean serum bilirubin values for G-6-P D deficient infants were higher than those values for normal premature and full-term infants and remained so for a more prolonged period. Ten of 26 infants studied (38%) had bilirubin levels of 20 mg% or above. Seven of the G-6-P D deficient infants (27%) were classed as premature, more than 3 times the rate for normal prematures.

514 PORTASYSTEMIC SHUNTS IN 102 PATIENTS WITH PORTAL HYPERTENSION. (E.) Sedgwick, C. E. (Lahey Clin. Found., Boston, Mass.), J. K. Poulantzas and W. H. Miller. New Eng. J. Med. 274(23):1290-1293, 1966.

Portasystemic shunts (40 portacaval and 62 splenorenal) were performed on 102 patients of whom 55 were classified as good risks, 42 as poor risks and 5 as emergency cases. The operative mortality rates in these preoperative groups were 9.0%, 33.3% and 60.0%, resp. The most common causes for death were liver failure and recurrent hemorrhage. The survival for 5 and 10 yr. in these groups was 67.5% and 38.8%, 33.3% and 11.1%, and 50.0% and none, resp. The following late complications occurred in the survivors: portasystemic encephalopathy, 22.5%; recurrent hemorrhage, 12.2%; peptic ulcer, 5.0%; and shunt thrombosis, 3.7%. It is concluded that the advantage of decreasing the risk of recurrent hemorrhage by a shunt operation

LIVER AND BILIARY TRACT

outweighs the disadvantage of the high operative mortality. Except for 12 patients, the age range of those treated was 30-69 yr. Only 7 patients had a normal liver, while 44 had portal or Laennec's cirrhosis, 20 had postnecrotic cirrhosis and 18 had biliary cirrhosis.

- 10515 AN AUTOMATED METHOD FOR THE DETERMINATION OF SERUM 5'-NUCLEOTIDASE. (E.) Hill, P. G. (East Birmingham Hosp., England) and H. G. Sammons. Clin. Chim. Acta 13(6):739-745, 1966.

An automated procedure for the estimation of serum 5'-nucleotidase (EC 3.1.3.5, 5'-ribonucleotide phosphohydrolase) for use with the Technicon Auto Analyzer is described as a diagnostic tool for evaluating liver function. The serum level of this enzyme is raised only in posthepatic or intrahepatic obstruction. The test is more specific than measuring alkaline phosphatase (EC 3.1.3.1, orthophosphoric monoester phosphohydrolase) as the latter enzyme increases in both bone and liver diseases. It is also a more sensitive indicator of biliary obstruction than is alkaline phosphatase. The 5'-nucleotidase activity is measured as the nickel-sensitive hydrolysis of adenosine-5'-monophosphate at pH 7.4 and the time incubation period is terminated by the addition of ethylenediamine-tetra-acetic acid. The results from the automated method were highly reproducible and correlated well with results obtained from Campbell's manual method.

- 10516 CORRELATION OF SERUM ENZYMES AND MORPHOLOGIC ALTERATIONS OF THE LIVER. WITH SPECIAL REFERENCE TO SERUM GUANASE AND ORNITHINE CARBAMYL TRANSFERASE (E.) Musser, A. W. (Duke U. Med. Sch., Durham, N. C.), C. Ortigoza, M. Vazquez and J. Riddick. Am. J. Clin. Path. 46(1):82-88, 1966.

Serum conc. of some enzymes was investigated in relation to liver pathology. Blood samples were also obtained from the donors of the bioptic specimens, 28 patients in hospital with the following diseases: (1) Laennec's cirrhosis, (2) chronic hepatitis, (3) postnecrotic cirrhosis, (4) hydropic degeneration, (5) cholangiolitis, (6) fatty change, (7) metastatic carcinoma, (8) hepatoma, (9) thorotrast deposition. The enzymes investigated were: guanase (G), ornithine carbamyl transferase (OCT), alkaline phosphatase (AP), serum glutamic oxalacetic transaminase (SGOT), and lactic acid dehydrogenase (LDH). Of these enzymes, G and OCT showed no correlation with the hepatic pathology presented. AP activity was determined by the automated method adapted by Marsh. SGOT was measured by the method of Babson *et al.* LDH was assayed by the Sigma procedure. Half the patients with Laennec's cirrhosis had elevated SGOT values considerably above the normal range; cirrhotic patients also had a tendency for increased AP; total LDH fell within normal range for all patients with Laennec's disease. Hepatitis patients had elevations beyond the normal ranges of SGOT and AP, but LDH was normal. Postnecrotic cirrhosis was normal with respect to SGOT and AP; this disease showed elevated LDH levels. Hydropic degeneration, cholangiolitis, and thorotrast deposition had all 3 enzymes well within the normal ranges. Fatty changes caused variability in AP and SGOT with normal LDH except in 1 case with about 4 times the max. normal. Metastatic carcinoma and hepatoma showed elevated SGOT and AP with normal LDH.

- 10517 INTRAHEPATIC TYPHOID CARRIERS. (E.) McFadzean, A. J. S. (Queen Mary Hosp., Hong Kong). Brit. Med. J. 1(5503):1567-1571, 1966.

Among 8 southern Chinese typhoid carriers followed for 2-16 yr. after cholecystectomy, the operation failed to eradicate the carrier state which was believed to result from intrahepatic foci of infection. Among 100 consecutive patients with recurrent pyogenic cholangitis, salmonellae were demonstrated in preoperative aspirations of bile fluid in 5 instances and ova of *Clonorchis sinensis* were also found in 3 of the 5. Following a review of other reports, it is concluded that typhoid carriers among the Hong Kong Chinese show a 1:1 sex distribution, with failure of cholecystectomy to eradicate the condition. The latter appears to involve intrahepatic foci of infection which are indistinguishable from the early lesions seen in pyogenic cholangitis due to *E. coli*. The absence of gallbladder carriers may be attributable to the rarity of chronic cholecystitis. A significantly higher than normal incidence of infection of the intrahepatic bile ducts by *C. sinensis* is also seen among typhoid carriers in this region, suggesting that

ER AND BILIARY TRACT

s liver fluke may play a contributory, although not a primarily causative, role. treatment thus far attempted has proved successful in correcting the carrier state these patients.

18 THE RESULTS OF HEPATIC LOBECTOMY FOR PRIMARY CARCINOMA OF THE LIVER.

(E.) Lin, T.-Y. (Nat. Taiwan U. Hosp., Taipei, Formosa). Surg. Gynec. Obstet. 123(2):289-294, 1966.

a total number of 121 patients 91 were considered to be operable for primary cinoma of the liver according to the following criteria: (1) sufficiently good rative risk, (2) no discernible metastasis in other organs, (3) palpable mass(es) any limited to one lobe of the liver, (4) the other lobe not cirrhotic or ular, (5) absence of jaundice or ascites, (6) no major hepatic dysfunction re- led by laboratory tests. On laparotomy, 49 patients appeared to be unresectable ause of severe cirrhosis or metastasis in contralateral lobe. Hepatic lobectomy possible in 42 patients, a resectability of 46.1% for those operated upon and 7% for the total number of patients. Of 42 lobectomies 24 were on the right e and 18 on the left lobe. The first operative step was the thoracoabdominal ision for adults or an upper transverse abdominal incision for infants and ldren. The second step was the division of the triangular, coronary and falcim ligaments to free the affected lobe from the diaphragm. The round ligament also divided, clamped and drawn to expose the cut end fully which aids in keep- the liver in a suitable position during resection. The third step was the ision of the hepatic capsule and direct insertion of the fingers into the enchyma to isolate the ductal and vascular trunks by finger fracture, smashing liver tissue. The branches of the hepatic artery, portal vein and hepatic duct the affected lobe were thus exposed to be clamped, doubly ligated and severed. iece of omentum was useful for covering the cut surface of the remaining liver. commonly reported risks during hepatic lobectomy are bleeding, cardiac arrest air embolism. In this series the operative course was uneventful in all but 5 ients; 4 of these were children who suffered cardiac arrest during the operation. heart beat resumed after external cardiac massage in all cases. Two patients lost on the first postoperative day because of prolonged brain anoxia. Of the patients who underwent lobectomy 37 survived the operation; 11 of these had rrosis. Of the 26 noncirrhotic patients, 16 died within the first yr., 1 within second, and 1 within the third postoperative yr. Metastasis was the cause of these late deaths except in 1 patient who died of cerebral hemorrhage 4 mo. er surgery. At the present time 8 noncirrhotic patients are well and are lead- active social lives. Only 2 of the 11 cirrhotics (23.8%) are still alive.

19 SYNDROME OF ENCEPHALOPATHY AND FATTY DEGENERATION OF VISCERA IN NEW ZEALAND CHILDREN. (E.) Becroft, D. M. O. (Princess Mary Hosp. Children, Auckland, New Zealand). Brit. Med. J. 2(5506):135-140, 1966.

total of 9 cases of a new syndrome, first described in Australian children, were n in New Zealand from 1959-1964. Ages ranged from 4.5 mo. to 5.5 yr.; 7 were s than 2 yr. old; there were 7 boys and 2 girls; 4 were European, 3 Polynesian, 2 mixed Polynesian and European. All children had grown and developed normally. were brothers aged 1.5 and 6.5 yr. Otherwise there was no known contact be- en cases, no record or past history of similar illnesses in the families, nor of er concurrent family illnesses. In most cases there was vomiting, followed by vulsions leading to coma, which was the major concern in all patients: 8 of 9 e unconscious or stuporous upon admission to hospital. There was no evidence shock; blood pressures were normal; temperature was up 1° in 1 child only. The rse of the disease was marked by a progressive disturbance of cerebral function ch appeared on the electroencephalogram (2 cases) as a severe, diffuse abnor- ity. Upon autopsy the brain was found to be swollen and edematous with flattened ebral gyri. There was no jaundice. At autopsy the liver was uniformly bright low or orange yellow due to fat present in small vacuoles in the parenchymal ls throughout the liver; these cells seemed normal in every other respect. The al cortex seemed swollen and pale in 8 cases; no necrotic conditions appeared the glomeruli or tubules. Other findings were: hypoglycemia of a severe grade urred in all except one case with blood sugar reported from 7-30 mg/100 ml in 8

LIVER AND BILIARY TRACT

patients and 84 mg% in 1 patient. Serum CO₂ content was low in 7 patients. Neutrophilic leukocytosis occurred in 6 patients with total WBC counts of 16,500 to 34,500 per 1 cubic cm. Bacterial cultures of blood and test cultures for virus proved negative. Three other cases, somewhat atypical, are also described. The etiology of the syndrome is unknown but the action of a hepatotoxin is considered most likely.

- 10520 PATHOLOGIC ANATOMY OF THE LIVER CAPSULE AS A BASIC CONSIDERATION IN LAPAROSCOPIC DIAGNOSIS. (Ger.) Elster, K. (U. Erlangen-Nürnberg, Germany) and H. Hüttinger. *Zschr. Gastroent.* 4(2):82-88, 1966.

Four types of macroscopic changes seen in the hepatobiliary capsule in autopsied subjects were found to possess differential diagnostic significance. Type I consisted of localized areas of dendritic fibrosis, accompanied by compression furrows running longitudinally and/or diagonally, lamination and inclusion of parenchymal elements. When fibrotic areas were diffuse, they indicated the presence of obstructive processes in the parenchyma and ascites was frequently demonstrable. When they occurred in concrescent strands or chains, they appeared to result from inflammatory processes. Type II consisted of roughness or unevenness of the capsule, which was clearly differentiated although somewhat narrower than usual, with very little cellular infiltration and no encroachment of biliary canaliculi. This type of change was seen only in the presence of hepatic cirrhosis, although there were no significant histologic changes in the capsule itself. Type III consisted of changes in color, due either to the presence of jaundice or to irregular distribution of the parenchymal blood supply. Type IV consisted of changes induced by hepatic metastases. Slight, but discernible fibrosis was seen above the site of subcapsular metastases. A relative (and occasionally considerable) thickening of the capsule, of a type never seen in connection with a liver disorder, indicated intracapsular spread of neoplastic cells, such as that seen in carcinomatous lymphangiopathy.

- 10521 SEROTONIN: DOES IT PLAY ANY ROLE IN PORTAL HYPERTENSION IN SCHISTOSOMAL HEPATIC FIBROSIS. (E.) Fikry, M. E. (Alexandria Fac. Med., United Arab Republic), M. El-Sayed and A. M. Nafie. *Acta Gastroent. Belg.* 29(7): 713-720, 1966.

Forty-eight patients suffering from portal hypertension as a result of bilharzial hepatic fibrosis were given serotonin (1) or the autoserotonin agent "Methysergid" to evaluate the role played by 1 in their hypertension. In 23 patients, 1 was inj. both i.m. and intrasplenically (10 mg each) and portal pressure was measured by the percutaneous trans-splenic route; observation was continued up to 50 min. Ten patients showed no pressure changes, 5 showed a pressor effect (of short duration in 2), and 8 showed a depressor effect (of short duration in 4 patients). In 16 patients portal pressures measured by the trans-splenic route before and after "Methysergid" was admin. (1 mg 3 times/day for 7 days) showed no change. Nine patients given "Methylsergid" i.m. (1 mg/day for 4 days) showed no portal pressure change in 3, a drop in 2 and a rise in 4. It is concluded that 1 cannot influence portal pressure in the portal hypertensive patient.

- 10522 WALDENSTRÖM'S CHRONIC ACTIVE HEPATITIS. (E.) Sherlock, S. (Royal Free Hosp., London). *Acta Med. Scand.* 179(Suppl. 445):426-433, 1966.

Among 561 patients with histologically-diagnosed cirrhosis of the liver, 139 had Waldenström's chronic active hepatitis, characterized clinically by persistent jaundice, spider nevi, acne, amenorrhea in younger women, and relative well-being until the terminal stages. Forty-eight per cent were between the ages of 10 and 29 yr., and 70% were female. Biochemical changes included hyperbilirubinemia, and high serum gamma globulin and transaminase levels. Liver histology showed aggressive fibrosis with isolation and death of small groups of cells, lymphocyte and plasma cell infiltration, and eventually a postnecrotic cirrhosis. Associated diseases including arthralgia, skin rashes, pulmonary infiltrates, ulcerative colitis, glomerulitis, diabetes, and Hashimoto's disease, were frequent. In approx. 25% of the patients, the onset simulated a typical attack of viral hepatitis. Lupus erythematosus cells were present in 15% of the patients. Incomplete studies on

LIVER AND BILIARY TRACT

effect of steroid therapy suggests that it relieves symptoms and decreases bilirubin and transaminase levels, but has no significant effect on liver histology and prognosis.

23 JAUNDICE IN THE AGED. (E.) Elmslie, R. G. (U. New South Wales, Kensington, Australia). Postgrad. Med. 40(1):103-106, 1966.

Twenty-seven aged jaundiced patients were studied over a 2-yr. period. Seventy-two per cent had a proved diagnosis of obstructive jaundice, which may usually be missed in the aged jaundiced patient with normal hemoglobin and negative history of other types of jaundice. Liver function tests are of limited value except that raised serum alkaline phosphatase favors obstruction. Confirmation can be by cholangiography or by direct inspection and palpation. Operative mortality was 6% in this series. In treatment, the patient must be adequately prepared, and a smooth postoperative course assured. Optimal metabolic, hematologic, blood vol., cardiorespiratory and renal status must be attained preoperatively and maintained. A transverse or oblique incision is the approach of choice due to low incidence of wound disruption, and closure should be attained with added tension sutures. The intrahepatic biliary tree should always be explored since the incidence of calculi in the common bile duct was 50% in this series. If the intrahepatic biliary tree is dilated and stones are present in common bile duct, the former should be explored and calculi by cholangiography, instrumentation, or choledochoscopy. These patients do not tolerate reoperation for missed calculi. Obstructions due to malignancy and cholecystitis should be treated by decompression, not excisional surgery. The metabolic and hepatic effects of biliary obstruction are relieved by anastomosis of the obstructed duct system to the alimentary canal. Obstruction of the pancreatic duct may be relieved by decompressing the pancreatic duct via a side-to-side anastomosis between the Roux loop of intestine draining the biliary system and the pancreatic duct.

24 CHANGES IN LIVER FUNCTION DURING MULTIPLE PREGNANCY--USING A MODIFIED BROMOSULPHTHALEIN TEST. (E.) Beazley, J. M. (U. Sheffield, England) and V. R. Tindall. J. Obstet. Gynaec. Brit. Comm. 73(4):658-661, 1966.

Modified sulfobromophthalein (BSP) tests by Tindall and Beazley (1965) were performed on patients with multiple pregnancies. These tests combined with chromatography will show alterations in the transfer of dye between plasma, liver and bile. In 8 multiple pregnancies only 3 showed greater than 2% BSP excreted in urine, which was negligible. The modified BSP test was performed on 10 patients with twin pregnancies, before and after pregnancy. An av. of 92% of the BSP was eliminated in bile and 8% returned to the plasma during the non-pregnant state; whereas, during pregnancy only 46% of the BSP was excreted into the bile, whereas 54% was returned to plasma. A comparison of 28 normal single pregnancies with 28 uncomplicated multiple pregnancies showed a significant reduction in rate of entry of BSP into liver cells in the multiple pregnancies. In single and twin pregnancies, when uncomplicated, no metabolites of BSP were found in plasma. Excretory function of liver returned to normal shortly after delivery of twins.

A METHOD FOR THE CONTINUOUS ANALYSIS OF SULFOBROMOPHTHALEIN IN LABORATORY ANIMALS. (E.) Archer, N. P. (Eli Lilly & Co., Greenfield, Indiana), E. C. Pierce and R. C. Anderson. Am. J. Clin. Path. 46(1):89-91, 1966.

A standard Technicon Autoanalyzer coupled with a range expander was utilized to obtain a continuous analysis of the quantity of sulfobromophthalein (BSP) present in blood. The only soln. (used as a diluent of the blood and as a recipient of the dialyzed blood) was made of 7.5 g NaCl and 5.0 ml of 40% NaOH brought to 1 liter with distilled water. For sampling, a piece of polyethylene tubing, 0.043 in. O.D. and 0.060 in. I.D. in size was used; it was connected directly to the pump and attached to an 18 gauge needle at the other end by passing the end through a hole in a small cap fitted inside the hub of the needle. A dose of 5 ml/kg body wt. of BSP containing 100 U of heparin was admin. via the cephalic vein; blood sampling was obtained from the saphenous vein. The continuous recording of the disappearance of BSP was obtained, together with the standardized values of BSP expressed as mg/liter.

In essentials the system comprises a proportionating pump for blood and reagent, a cactus bubbler to control air supply, double dialyzer, mixing coil, colorimeter, range expander and recorder. The system is capable of giving a precise and functional concept of the disappearance of BSP from the blood of laboratory animals.

- 10526 THE ULTRASTRUCTURE OF THE HUMAN LIVER IN DIFFERENT TYPES OF IDIOPATHIC CHRONIC JAUNDICE. III. PIGMENTED INCLUSIONS IN THE SYNDROMES OF GILBERT ROTOR, AND DUBIN-JOHNSON. (Fr.) Minio, F. (U. Lausanne, Switzerland), A. Gautier and P. Magnenat. *Zschr. Zellforsch.* 72(2):168-183, 1966.

Liver biopsies from 13 patients with nonhemolytic, constitutional jaundice of 3 types (6 cases of Gilbert's, 2 cases of Rotors, and 5 cases of Dubin-Johnson's disease) were studied with reference to pigment inclusions in the liver cells. The biopsy specimens were divided and one sample of each was prepared for light microscopy by the usual technics. The other samples were prepared for electron microscopy by osmic tetroxide and glutaraldehyde fixations, alone and in combination in buffered soln. The histology, conventional cytology and ultrastructure of the liver in the 5 cases of the Dubin-Johnson disease were indistinguishable from normal liver tissue in all constituents except the pigmented inclusions in the cytoplasm of almost all hepatocytes. A granulous-filamentous component is prominent in these inclusions which are globular in shape and probably lipid in nature. The same type of inclusion occurs in Gilbert's disease where the lipid seems to be lipofuscin and in which the granules and filaments are fewer than in the Dubin-Johnson inclusions. These inclusions react identically to the various technics of fixation and staining. In Rotor's syndrome other pigment inclusions are present which are not detectable in ordinary histological preparations; they consist essentially of aggregates of dense, ferritin-like material. The presence, in the hepatocytes, of pigment inclusions which have some features in common in the 3 types of syndromes and other properties specific for each of them confirms the close relationship among these types of jaundice, but still emphasizes their differences; in addition the ultrastructures observed underline the difficulty of an exact classification of these syndromes.

- 10527 AN EXPERIMENTAL STUDY OF AUGMENTATION OF THE FUNCTIONS OF THE PORTAL SYSTEM BY LIVER TRANSPLANTS WITH THE HOST LIVER IN SITU. (Fr.) Michoulier J., L. Bernard, J.-C. Imbert, J. Foray and J. Leroy. *Mem. Acad. Chir.* 92(20-21):548-554, 1966.

After a number of trials of liver grafts with various vascular circuits to supplant the normal arterial and portal blood supply and to return hepatic venous blood to the systemic venous system of the host while the host liver remained in situ, the final method adopted was the following: (1) The site chosen for the transplanted lobes was median longitudinally and left laterally in the abdomen. (2) A segment of the donor vena cava into which the hepatic veins enter was anastomosed at its caudal end with the postcava of the host. (3) After clamping the aorta laterally, the hepatic artery of the graft, severed as close to the celiac trunk as possible, was implanted into the aorta. (4) The end-to-end anastomosis of the splenic vein of the host and the portal vein of the graft was completed. (5) Finally the bile duct was implanted into the nearest portion of the ileum. Special attention should be paid to the caval anastomosis and to ligate severed blood vessels. Of 28 transplants, 19 survived for at least 48 hr. Five dogs were deliberately sacrificed between 2 and 5 days, for functional studies, histology, and angiography to compare the host and donor livers, and especially to check the circulation of the grafts. Two dogs died of necrosis and infection, one on day 3, the other on day 6. Three animals were definitive survivors; one was sacrificed on day 32, another on day 90 and the third on day 150. In each of these three animals the graft had been completely resorbed. Also, leukocytosis which in some cases showed very high WBC had returned to normal, as had the hematocrit and serum transaminase conc.

- 10528 CARBOHYDRATE METABOLISM DISTURBANCES IN HEPATOLENTICULAR DEGENERATION. (E.) Luca, N. (Inst. Neurol., Bucharest) and V. Ionașescu. *Rev. Roum. Neurol.* 2(4):281-285, 1966.

VER AND BILIARY TRACT

n patients (7 males and 3 females between 16 and 30 yr. old) with hepatolenticular sease (HLD), confirmed by biochemical tests and ophthalmologic examination, higher pper and amino acid conc. in urine, and the presence of the corneal ring of Kayser-eischer, were given 50 g of glucose each p.o. in a glucose tolerance test (GTT). e compounds assayed at 0, 30, 60 and 120 min. after ingestion of sugar were:) blood sugar, (2) pyruvic acid, (3) aldolase, (4) lactic acid, (5) inorganic osphorus and (6) potassium. The HLD patients had a moderately low glucose larence. During GTT the pyruvic, lactic acid, and aldolase curves were abnormal. ginning with normal fasting values a decrease of pyruvic acid occurred instead an increase; a decrease followed by a subnormal increase in lactic acid took ace; no change in aldolase level was found during the first 90 min. following ich there was a sudden decrease in serum aldolase. Inorganic P and K serum vels remained within normal limits. The kinetics of carbohydrate metabolism were vestigated in 4 HLD patients and 4 controls with the finding that glucose and odanate spaces were normal; however, glucose return time was much extended 2.6 min. as compared to 31.5 min. in the controls). Standard cellular glucose nsumption in patients was depressed (4.8 as compared to 10 mg/kg/min. in controls).

529 ACTIVITY OF MITOCHONDRIAL AND CYTOPLASMIC ENZYMES IN SERUM FROM PATIENTS WITH VARIOUS LIVER DISEASES. (It.) Notarbartolo, A. (U. Palermo, Italy), F. Giglio, S. Le Moli, P. Citarella, G. Migneco and L. Pagliaro. Boll. Soc. Ital. Biol. Sper. 42(7):328-331, 1966.

rum activity of 3 mitochondrial enzymes: glutamic dehydrogenase (GDH), ornitho-rbaryl transferase (OCT), and the cationic fraction of glutamic-oxalacetic trans-inase (GOT), and 4 soluble cytoplasmic fraction enzymes: anionic fraction of T, sorbitol dehydrogenase (SDH), phosphoglucoisomerase (PGI), and glutamic pyruvic ansaminase (GTP), were studied in 35 normal subjects and in 251 others with vere liver disturbances. Increased activity of all 7 enzymes was noted in acute patitis, particularly in the initial phases. SDH increased in acute viral hepatis and neoplastic liver cases from 5 ± 1 to 1019 ± 948 and $215 \pm 275 \mu\text{U}$, resp. derate increases of the mitochondrial enzymes in patients with cirrhosis and patitis did not vary much, while lower and more variable activity was observed in of the 4 supernatant enzymes (GOT, SDH, and GTP). The increase in PGI paralleled at of the mitochondrial enzymes. A different enzymatic pattern accompanied hepatic seases, not only in the individual enzyme increases but also in the relative in-eases of the intra- and extramitochondrial enzymes. The ratio of the mitochondrial soluble fraction enzymes (mean value for the enzymes studied) was 0.29 in viral patitis, 2.42 in cirrhosis, 0.52 in the neoplastic liver, and 0.48 in liver asis.

530 EXPERIMENTAL AND CLINICAL STUDIES ON THE INTRAHEPATIC VASCULAR CHANGES IN CHRONIC LIVER INJURY. II. RADIOLOGICAL OBSERVATIONS IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (E.) Tamao, H. (Okayama U. Med. Sch., Japan). Jap. Circ. J. 30(4):297-308, 1966.

erty patients with chronic hepatitis or liver cirrhosis were selected to devise an alytical method sensitive enough to detect alterations in venographs of hepatic d portal venous branches, with special reference to chronic hepatitis. These es were separated into 4 groups on the basis of their hemodynamics and peritoneo-opic findings: Type I (2 cases), characterized by a whitish wrinkle formation on e surface of the liver (without any other signs); Type II (6 cases), with hepato-galy and edges of liver rounded; Type III (19 cases), with dilated superficial ssels visible on the surface of the liver and splenomegaly (the sign of portal pertension); and Type IV (4 cases), with small scars visible on the surface of e liver; 9 patients were cirrhotic. Hepatic and portal venography were also rried out in normal subjects. Two methods are described for each technic for the i. of radioactive contrast material. The diameters of the veins were measured, ginning with the largest vein draining definite segments of the liver through 4 odivisions of the vein in hepatic venography. The measurement of portal vein ameter was more difficult because of dilution of the contrast material by blood. rograde portography was successful in 50% of cases. The portal measurements e made in the same way as those on the hepatic veins. An increase in the diam-ers of branches of the portal vein (4 and 5 divisions) was observed in Type

III chronic hepatitis; a decrease in diameter of veins in the distal region of the fourth division was observed in Type IV chronic hepatitis. In cirrhosis, narrowed diameters were observed in almost all subdivisions of both the hepatic and portal veins. Narrowing seemed to occur first in peripheral vessels.

- 10531 THE EFFECT OF α -TOCOPHEROL ACETATE ON PLASMA ESTERIFIED CHOLESTEROL IN PATIENTS WITH CHRONIC LIVER DISEASE. (E.) Blazek, Z. (Inst. Nutrition Res., Bratislava, Czech.) and A. Dvorsky. Nutr. Dieta (Basel) 8(2): 100-108, 1966.

In order to determine the effectiveness of vitamin E (α -tocopherol acetate) as a treatment for cirrhosis and fatty liver α -tocopherol acetate was admin. (500 mg/d) to 19 patients with chronic hepatitis and compensated cirrhosis, and histories of infectious hepatitis. Cholesterol and cholesterol ester levels in blood was determined at the beginning and end of a 10-day treatment period. There was a statistically significant rise (5-slightly over 40%) in the plasma cholesterol ester fraction after 10 days of α -tocopherol acetate treatment in 15 of the 19 patients. The effect of γ -tocopherol on serum cholesterol was highly variable, and no significant effect was noted. The suggested mechanism of action of γ -tocopherol was at the level of key enzyme reactions in the liver and in protecting unsaturated fatty acids, thereby increasing their serum level.

- 10532 EVALUATION OF BLOOD EXCHANGE IN THE TREATMENT OF HEPATIC COMA. (E.) Berger, R. L. (Tufts U. Sch. Med., Boston) and F. Stohlmán, Jr. Am. J. Surg. 112(3):412-418, 1966.

Results from 9 patients with hepatic coma (of 1-3 days duration) receiving 1 or more exchange transfusions (usually 1 or 2; 1 patient required 7) indicate that this method is simple, relatively safe and promising for the treatment of acute fulminating hepatitis. Eight of the 9 patients regained consciousness 1-3 days after treatment, but only 6 were long-term survivors (including the patient receiving 7 transfusions). One patient died with severe hypotension 3 days after regaining consciousness, and another died 30 days later from septicemia. The exchanges were done serially in 500-ml aliquots exchanged with an equal amount of fresh heparinized whole blood, infused under pressure. When normovolemia was reestablished, the heparin was neutralized with protamine sulfate. The usage of fresh blood aided in correcting serious coagulation defects. In addition, the rate of decrease in bilirubin, serum glutamic-oxalacetic transaminase and alkaline phosphatase exceeded the calculated plasma exchange curve, suggesting that these and possibly other substances were not only removed from the plasma but also extracted from the tissue.

- 10533 RESEARCH ON THE PHYSIOPATHOLOGY OF THE LIVER IN CONGENITAL CYANOTIC CARDIOPATHY. III ANALYSIS OF THE HEPARIN TOLERANCE TEST. (It.) Trisotti D'Ambrosio, R. (Riuniti Child. Hosp., Naples, Italy), E. Salmoni and A. Ricciardi. Rass. Int. Clin. Ter. 46(9):456-458, 1966.

In vitro heparin tolerance tests (according to the method of Soulier and Le Bellock) were performed on 32 untreated, fasting patients with congenital cyanotic heart disease. In 22 patients the test was within normal limits, heparin tolerance was decreased moderately in 4 cases and markedly in 8. It is concluded that the heparin tolerance is useful for detecting minimal disturbances of liver function due to local hypoxia.

- 10534 A STATISTICAL APPROACH TO THE DIAGNOSIS OF LIVER DISEASE ON THE BASIS OF SERUM BILIRUBIN AND ENZYME LEVELS. (E.) Fellingham, S. A. (Nat. Res. Inst. Math. Sci., Pretoria, South Africa) and R. C. P. M. Mekel. S. Afr. Med. J. 40(22):520-523, 1966.

Total and conjugated bilirubin and the activity of 6 serum enzymes (aldolase, isocitric dehydrogenase, lactic dehydrogenase, glutamic-oxalacetate transaminase, glutamate-pyruvate transaminase, and alkaline phosphatase) were determined in 194 patients with liver disease. On the basis of liver biopsy, the patients were divided into 5 groups: I, hepatitis and necrosis; II, siderosis, hepatofibrosis, and cirrhosis; III, hepatoma; IV, pneumonia with jaundice; and V, miscellaneous. The statistical technic of discriminatory analysis was applied to the data to

termine whether definite patterns existed which could enable the clinician to make a reliable diagnosis on the basis of the serum values. A linear equation in variables was calculated for each group, the constants of these equations being determined so as to result in max. distinction between the groups. Use of these equations correctly classified 120 of the 194 patients (Group I: 14 of 24, II: 52 of 52, III: 31 of 50, IV: 11 of 19, V: 12 of 49); 45 patients, including many from Group V, had been incorrectly placed in Group II. A separate analysis of Group V showed significant differences between the 4 subgroups. It is concluded that discriminatory analysis could be valuable in clinical diagnosis, the value of the present results, however, being limited to hepatoma (Group III) since other groups could be better diagnosed clinically or included too many incorrectly placed patients.

35 CHANGES IN BLOOD COAGULATION AND FIBRINOLYSIS IN RELATION TO THE DEGREE OF HEPATOCELLULAR DAMAGE IN PATIENTS WITH HEPATIC DISEASE. (It.) (Rev.) Cocchieri, S. (U. Bologna, Italy), P. Fiorentini, L. Lodi and P. Gennari. Fegato 12(1):45-52, 1966.

Hepatic Injury

- 10630 FINDINGS FOLLOWING PERFUSION OF THE ISOLATED LIVER WITH HALOTHANE. (Ger.) Rittmeyer, P. (U. Hamburg, Germany) and K. Schilling. Anaesthesist 15(5):157-160, 1966.

Thirty rabbits (2.0-3.5 kg) were laparotomized under Nembutal anesthesia, their small intestines exteriorated in entirety into a moist plastic bag into which an halothane-O₂ mixture was introduced in increasing conc. of up to 4.0 vol.% under a slight positive pressure to facilitate resorption. Blood specimens from the portal vein (since the entire blood supply of the intestinal serosa returns through this vessel), the superior vena cava and the aorta were taken from 5 animals and analyzed for halothane content by gas chromatography. The portal vein showed 10 times more halothane than usually found in the venous blood of patients under narcosis. Halothane conc. in the aorta was lower due to mixing with blood received from the liver; after passage through the lungs, arterial blood contained only traces of the narcotic. Four animals (controls) were perfused with O₂ alone, 21 with halothane, as above. Liver specimens were taken from this group before perfusion, and after perfusion at hourly, later daily intervals for up to 9 wk. Three of the 4 O₂-perfused controls were also perfused with halothane 4-8 wk. after the first operation, and 4 of 21 rabbits of the test group received a second halothane perfusion 4-9 wk. after the first. No liver damage could be demonstrated by light or electron microscopy. Prior to the perfusions 80% of the animals had primary liver damage (chronic periportal inflammations, parasitic in 12; peripheral fatty deposits in 6; biliary cirrhosis and pseudotuberculosis in one each). It is concluded that it is possible to increase halothane conc. in the liver without necessarily deepening the general anesthesia.

- 10631 VISUALIZATION OF INTRAVENOUSLY INJECTED 9,10-³H₂-PALMITIC ACID IN RAT LIVER BY ELECTRON MICROSCOPIC AUTORADIOGRAPHY. (E.) Stein, O. (Hebrew U. Sch. Med., Jerusalem, Israel) and Y. Stein. Israel J. Med. Sci. 2(2):239-242, 1966.

Following a 16-hr. fast, female rats were admin. ethanol by a stomach tube (0.6 g/100 g body wt.) and then, 4 hr. later, 9,10-³H₂-palmitic acid was inj. into the tail vein in order to visualize the site of esterification of tritiated palmitate and to localize this labeled lipid in ethanol-induced fatty liver. Two, 5 and 10 min. following the inj. the radioactivity in the liver was found predominantly in the triglycerides. The autoradiographs made 2 min. after the inj. showed that the label was localized over the area of the endoplasmic reticulum, indicating this as the site of palmitate esterification. Ten min. following inj., autoradiographic grains were seen in the main lipid pool and also over small lipid droplets in the Golgi apparatus and in the cisternae of the smooth endoplasmic reticulum.

- 10632 THE EFFECTS OF HALOTHANE ON RAT LIVER MITOCHONDRIA. (E.) Snodgrass, P. J. (Harvard Med. Sch., Boston, Mass.) and M. M. Piras. Biochemistry (Wash.) 5(4):1140-1149, 1966.

When incubated with normal rat liver mitochondria, halothane (admin. by varying the volume of 0.25 M sucrose saturated with halothane) uncoupled oxidative phosphorylation, induced irreversible swelling, abolished the 2,4-dinitrophenol-stimulated adenosine triphosphatase (ATPase) activity and caused a marked decrease in K content. Halothane inhibited the oxidation of diphosphopyridine nucleotide-linked substrates, yet reduced diphosphopyridine nucleotide (DPNH) was oxidized in the presence of the hydrocarbon. This DPNH oxidation was uncoupled from phosphorylation and was blocked by amytal. Using various substrates, halothane uncoupled at all these phosphorylation sites. After oral admin. of halothane to rats, no impairment in mitochondrial function was detected.

- 10633 LIVER BIOPSY, THE DOUBLE DYE TEST AND BILIGRAFIN EXCRETION. (Ger.) Bargon, G. (U. Giessen, Germany). Fortschr. Roentgenstr. 104(6):790-795, 1966.

LIVER AND BILIARY TRACT

Hepatic Injury

The relationship and possible correlation between morphologic liver damage, proven by biopsy, the sulfobromophthalein (BSP)/Trypan Red (TR) test (considered by the author to be 97.8% accurate in reflecting parenchymal damage), and the biligrafins-cholangiogram were investigated in 248 patients representing 3 groups: Group 1, 201 patients with liver damage established by biopsy (71 chronic hepatitis; 20 precirrhotics; 44 cirrhotics, 53 with fatty liver, and 15 with various liver metastases); Group 2, 32 patients who underwent i.v. cholangiography first (because of abdominal complaints), then followed by the BSP test and biopsy; Group 3, 15 cardiac patients with considerable liver involvement. No biopsies were performed in these patients. Although all the 201 of Group 1 had positive histology and positive BSP tests, 126(63%) had normal biligrafin (BG) excretion, 25/126 were among the cases with the most severe parenchymal damage. The BG test in 64/201 (32%) was indicative of liver abnormalities (contrast shadow weak, and/or appearing late), even though 19 of these (3 hepatitis in full remission and 16 fatty livers with only minimal morphological changes) were the least severe cases. Only in 11 (5%) was the cholangiogram negative. While normal BG excretion was found in the 14 cases with the most severe histologic changes, BG excretion was normal also in 14 of the lowest BSP values (below 65%). Eight patients with defective BG clearance had almost normal BSP values (above 80%). The 32 patients of Group 2, all with abnormal BG tests, included 22 cases of parenchymal damage and 10 with inflammatory conditions. Correlation between the BG test and histology + BSP test was found in only 23/32 (72%). Of Group 3 patients 5/15 had normal cholangiogram, 6/15 had reduced or decreased BG excretion, and the test was negative in 4/15. All of these patients had very severe parenchymal damage and BSP values between 15-40%. In all groups, only 24 cases (10%) of the Groups 1 and 2 had negative BG tests, with the contrast media being excreted through the kidneys. The data indicate that BSP and biligrafin have different excretion mechanisms, which may be damaged independently of each other. A positive cholangiogram does not exclude liver damage, while an abnormal one is at most, suggestive only of the presence, but not of extent or severity of damage. Only a negative cholangiogram can be taken as a certain sign of liver involvement.

- 0634 RELATIONSHIPS OF BIOTIN TO ETHIONINE-INDUCED FATTY LIVER. (E.) Marchetti, M. (U. Bologna, Italy), V. Ottani and P. Puddu. *Arch. Biochem.* 115(1): 84-86, 1966.

Male weanling rats (40-45 g) were divided into 2 groups of 32 each. One group was fed on a biotin-free diet, the other on a biotin-supplemented diet. After 60 days 16 animals of each group were inj. i.p. with DL-ethionine (75 mg/100 g body wt.); the other 16 animals (controls) from each group were inj. i.p. with saline. This resulted in 4 groups of 16 animals each: (1) control, (2) control plus ethionine, (3) biotin-deficient and (4) biotin deficient plus ethionine. All animals were killed 24 hr. after inj. and the livers saved for determination of the effect of ethionine on (a) hepatic levels of biotin; (b) the levels of cholesterol, phospholipid, neutral fat, and total lipid in the liver, and (c) the incorporation of acetate-1-C¹⁴ *in vitro* into the lipid content of rat liver slices. Total lipids were measured gravimetrically; cholesterol was analyzed by the method of Sperry and Webb. Phospholipids were determined by quantitative analysis for phosphorus. Biotin was assayed microbiologically by the growth rate of a selected strain of *Streptococcus arabinosus*. After incubation of liver slices in a medium containing the labeled acetate, the liver slices were thoroughly rinsed, homogenized and extracted; evaporation of the extract yielded the lipid residue which was dissolved in chloroform for radioactivity measurements in a windowless gas-flow counter. Results were: (a) biotin, in µg/g wet wt. of tissue, was in the resp. animal groups: (1) 2.94, (2) 1.40, (3) 0.47, (4) 0.50. (b) Neutral fat was significantly increased in ethionine-treated rats receiving supplemental biotin (Group 2). No significant change was found in cholesterol and phospholipid conc. in the 4 groups. (c) Groups (2), (3) and (4) had greatly depressed incorporation of labeled acetate into liver fat, actually less than 1/4 as compared to control Group 1.

- 0635 PATHO-ANATOMICAL CHANGES AFTER CLOSED LIVER INJURY. AN EXPERIMENTAL STUDY IN DOGS. (E.) Grimelius, L. (U. Uppsala, Sweden) and G. Hellström. *Acta Chir. Scand.* 131(6):485-494, 1966.

Adult dogs (26) were submitted, under anesthesia, to 2 degrees of trauma, 1 with impact energy of 5 kg and the other with impact energy of 15.5 kg. The intervals between impacts were usually 5-10 min. and the trauma was applied on the right side midway between the xiphoid process and the umbilicus. Three control dogs were not exposed to trauma, but were bled to death and autopsied immediately. In 4 dogs only the liver was examined microscopically. The control dogs bled to death for 1-15 hr. revealed small hemorrhages in the lung, brain and spleen, whereas, the dog bled over a period of 5.5 hr. showed no hemorrhages. In 2 controls, isolated fat emboli were noted in all organs examined. All 3 controls showed contracted spleen and partly atelectic lungs. In 23 dogs with trauma, rupture of liver occurred in all cases. In general, increasing number of traumas resulted in an increase in extent of liver damage, but no correlation existed between extent of liver rupture and the different degrees of trauma used. The lesion was in the right lateral and/or medial lobe. Max. lesions occurred in 13 dogs. Extensive hemorrhage existed in all dogs with multiple trauma, while little bleeding occurred in 4 cases with only 1 trauma. Fat emboli were present in the hepatic vessels of 12 dogs. Lesions in other organs and pathogenesis are discussed.

- 10636 ISOLATION AND CHARACTERISATION OF HEPATOTOXINS FROM Penicillium rubrum. (E.) Townsend, R. J. (Tropical Products Inst., London), M. O. Moss and H. M. Peck. J. Pharm. Pharmacol. 18(7):471-473, 1966.

Penicillium rubrum M.R. 048 was grown on a malt enriched Raulin Thom medium in stationary cultures at 28-30° C for 13 days, harvested on day 13, and conc. to a small vol. under reduced pressure; the mass of mold was extracted with ethanol and then with acetone; the acetone and alcohol contained the toxin; after evaporation of the solvents, the residue was partitioned between ethyl acetate and water. The ethyl acetate phase which contained most of the toxin was evaporated to dryness, leaving a pale orange gum which became a buff powder when washed with sodium dried diethyl ether. The crude toxin had a melting point of 126-146° C (with decomposition), specific rotation sodium D line +32.5°, LD₅₀ 3.75 mg/kg (i.p. mice), very soluble in acetone, soluble in alcohols, slightly soluble ether, insoluble in chloroform and cold water. Careful precipitation yielded the highly toxic Rubra toxin A and Rubra toxin B. The crude toxin in doses well above the LD₅₀ caused death in mice within 2-4 hr. of admin. Postmortem examination disclosed an extensively hemorrhaged liver with a mottled appearance which seemed to be characteristic of P. rubrum toxin; the kidneys were slightly anemic; the lungs occasionally showed hemorrhages. Mice killed 7 days after a sublethal dose of the toxin showed no macroscopic liver damage; mice dosed similarly but killed 24 hr. after inj. had the typically mottled liver. Recovery from a sublethal dose seems to occur within 7 days. The sleeping time test (sodium pentobarbitone, 45 mg/kg inj. i.p.) indicated a rapid onset of interference with the normal detoxicating mechanism. This reached a peak 2 days after admin. of a sublethal dosage of toxin and then decreased. The increased effectiveness of the pentobarbitone (increased sleeping time) resulted from a decreased rate of detoxification of the anesthetic.

- 10637 NODULES IN THE LIVERS OF C₃H MICE AFTER LONG-TERM CARBON TETRACHLORIDE ADMINISTRATION: A LIGHT AND ELECTRON MICROSCOPIC STUDY. (E.) Confer, D. B. (U. Cincinnati Gen. Hosp., Ohio) and R. J. Stenger. Cancer Res. 26(5):834-843, 1966.

The ultrastructure of CCl₄-induced nodules (0.1 ml of 40% soln. rectally twice weekly for 20-26 wk.) in the livers of C₃H mice compared as follows with normal parenchyma: the nodules' cells exhibited enlarged mitochondria, hypertrophied microbodies, prominent Golgi complexes and abundant dilated rough-surfaced endoplasmic reticulum with numerous attached ribosomes. It is believed that the latter type of reticulum reflects metabolic activity rather than cellular injury and that the total morphologic picture suggests that the nodules represent areas of hyperplasia rather than neoplasia. Histologically, the nodular cells were comparable in many ways to livers of untreated animals. These induced nodules varied from 4-14 mm in diameter and were sharply demarcated from the adjacent parenchyma. They contained occasional biliary ductules and scattered blood vessels resembling capillaries.

638 CHANGES IN THE TRANSAMINASE AND PHOSPHATASE ACTIVITY OF THE BLOOD AND THE OCCURRENCE OF HAEMOBILIA FOLLOWING EXPERIMENTAL LIVER TRAUMA IN THE RABBIT. (E.) Risholm, L. (Sahlgrenska Hosp., Göteborg, Sweden) and L. Sullivan. *Acta Chir. Scand.* 131(6):495-498, 1966.

Forty rabbits with severe trauma of the liver, 10 animals with 10% and 10 with 5% traumatization (standardized) were used as experimental animals to study the occurrence of hemobilia in terms of occult blood, and to study changes in blood conc. of 3 enzymes: glutamic-oxalacetic transaminase (GOT), glutamic-pyruvic transaminase (GPT) and alkaline phosphatase (AP) as a result of the hepatic trauma. Occult blood, determined by the benzidine reaction, was found in the feces of every experimental animal, persisting usually for several days after injury to the liver. The serum levels GOT and GPT rose rapidly, reaching their peaks within 2 hr., tending to be proportionate to the degree of trauma (5 and 10%). At these degrees of trauma there was no change in serum conc. of AP. However, with severe trauma, serum conc. of AP did increase and the serum levels of GOT and GPT were much higher than with 10% traumatization. It is suggested that serum transaminase determinations may be a diagnostic aid when traumatic liver damage is suspected.

639 THE ACTIVITY OF GLUTAMIC-OXALACETIC AND GLUTAMIC-PYRUVIC TRANSAMINASES (GOT AND GPT), ORNITHINE-CARBAMOYL-TRANSFERASE (OCT) AND ALKALINE PHOSPHATASE (AP) IN SERUM IN CLOSED LIVER INJURY. AN EXPERIMENTAL STUDY IN DOGS. (E.) Hellström, G. (U. Uppsala, Sweden). *Acta Chir. Scand.* 131(6):476-484, 1966.

Forty mongrel dogs (19) of both sexes were anesthetized, cannulated for blood sampling, and supplied i.v. with an av. of 350 ml of 6% dextran soln. 1 hr. each. These 17 received graded closed liver injury produced by a wt. of 15.5 kg dropping in pendular motion to strike on the right side halfway between the xiphoid process and the umbilicus. Muscle trauma only was produced in 2 dogs which served as controls by dropping the wt. on the right thigh. Normal serum conc. were established for a number of enzymes: glutamic-oxalacetic and glutamic-pyruvic transaminases (GOT and GPT, resp.), ornithine carbamyl transferase (OCT), and alkaline phosphatase (AP). Immediately after traumatization, and at hourly intervals for 5 hr., blood samples were taken for determination of enzyme conc. GOT and GPT increased above the normal value with a distinct tendency for the increase to be proportionate to the degree of trauma. With muscle trauma alone there was no increase. Serum OCT was determined in only 9 dogs; the results were more variable, showing only a slight tendency to increase. In no case did AP increase above the normal limits of variation.

640 PATHO-ANATOMICAL CHANGES AFTER CLOSED LIVER INJURY. AN EXPERIMENTAL STUDY IN DOGS. (E.) Grimelius, L. (U. Uppsala, Sweden) and G. Hellström. *Acta Chir. Scand.* 131(6):485-494, 1966.

Twenty-six adult dogs of both sexes, including 3 controls, with an av. body wt. of 15 kg were anesthetized and maintained under anesthesia until death while receiving an av. dose of 350 ml/hr. of 6% dextran soln. during the course of experimentation, and for the experimental animals was traumatization of the liver by 2 degrees of impact force. The traumatic shocks were varied in number and in time interval between shocks which were applied on the right side midway between the xiphoid process and the umbilicus. In 12 dogs intravascular pressure measurements were taken during traumatization. The 3 control dogs, exsanguinated at set rates for periods of 1-5.5 hr., received no trauma. All dogs were necropsied and pathological findings recorded. In 4 dogs the liver was examined microscopically. In 19 dogs samples were taken from the right lateral and median lobes of the liver, from the spleen, right kidney, right adrenal gland, upper lobe of right lung, right auricle and the ventricular septum, aorta at the ligamentum arteriosum, and from the left ventral lobe for histologic studies. In 15 dogs examination was made for fat emboli in samples from liver, kidney, lung and ventricular septum. Two control dogs exsanguinated in 1.5 hr. showed small hemorrhages in various capillary beds. This did not occur in the third control bled over a period of 5 1/2 hr. Light to severe rupture of liver occurred in all experimental dogs; hemorrhages occurred in border zones between connective tissue and parenchyma; fat content of the liver was

increased and in 12 dogs there were fat emboli in hepatic vessels. The spleen was greatly contracted and ischemic in all dogs with parenchymal hemorrhage in 10. Right kidney damage consisted of 1 rupture in 1 dog, microscopic hemorrhages in 11 and fat emboli in 7. Bleeding occurred in or close to the right adrenal gland in all cases. Lung hemorrhages were common with blood in alveoli even in the left upper lobe, and fat emboli were found in all 15 dogs studied for emboli. Atelectasis was present. Slight subendocardial bleeding was found in 1 dog and minor interstitial bleeding in 2. Slight bleeding was evident in interventricular septum of 4 dogs. Aorta appeared normal in all cases. The left cerebral cortex showed petechiae in 10 dogs. In every case there was blood in the peritoneal cavity (550-1800 ml). Hemorrhages in distant sites were due mainly to pressure surges via the venous system resulting from compression of vessels by impact force.

- 10641 LESIONS ASSOCIATED WITH CLOSED LIVER INJURY. A CLINICAL STUDY OF 192 FATAL CASES. (E.) Hellström, G. (U. Uppsala, Sweden). Acta Chir. Scand. 131(6):460-475, 1966.

A report on the injuries occurring in the absence of direct trauma concomitantly with closed liver injury. This association of compression injury of the liver with other injuries, especially to the vascular system is of considerable importance. In 192 fatal cases of transcapsular liver rupture 60 cases died immediately or en route to the hospital; 65 died during the first 12 hr. and the remaining 67 died later. Associated injuries, without signs of external trauma, were (with the number of cases of each kind): intracranial petechiae, 9; bloody cerebrospinal fluid, 9; temporary loss of consciousness, 9; rupture of right atrium, 4; subendocardial hemorrhage, 7; circulatory failure, 39; aortic rupture, 6; pulmonary hemorrhage, 15; fat embolism, 5; not identified, 13. It should be noted that the vascular ruptures listed above may result from the sudden pressure wave caused by hepatic compression, and passing out over the vascular system. Sudden organ displacement may have effects separate from the blood vascular system. Sudden cardiac displacement can cause irregularities in rhythm or even cardiac arrest.

- 10642 CHANGES IN THE TRANSAMINASE AND PHOSPHATASE ACTIVITY OF THE BLOOD AND THE OCCURRENCE OF HAEMOBILIA FOLLOWING EXPERIMENTAL LIVER TRAUMA IN THE RABBIT. (E.) Risholm, L. (Sahlgrenska Hosp., Göteborg, Sweden) and L. Sullivan. Acta Chir. Scand. 131(6):495-498, 1966.

Liver trauma was inflicted in two ways: In method 1, 1-3 of the liver lobes were compressed digitally to crush the liver substance without rupturing the capsule. The capsule was then punctured and sutured. Method 2 employed the use of forceps to inflict slighter and more standard trauma. The vol. of defect was measured and compared with liver vol. to assess the relative size of the traumatized area. One lobe was traumatized in 10 experiments and 2 lobes in 10 others. Blood samples were taken from the ear vein after 1, 2, and 3 hr. and after 1, 2, 3, and 4 days. Glutamic oxalacetic transaminase and glutamic pyruvic transaminase activities were determined by Karman's method (1955) and alkaline phosphatase activity was determined by the method of Buch and Buch (1939). No elevation of the alkaline phosphatase was noted in any of the experiments where only slight trauma was inflicted, but was markedly elevated where trauma was extensive (Method 1) in 4 rabbits. The transaminase levels rose rapidly and peaked within a few hr. The rise was disproportionate to the extent of trauma. Ten rabbits without liver trauma served as controls and no enzyme rise was noted. Biliary fistulas were created in 2 ways prior to traumatic liver damage, both of which yielded hemobilia even before the damage due to biliary tract initiation by the catheter. Thus, the presence of occult melena as found in every instance was determined with the benzidine test and used as a criterion of posttraumatic hemobilia. It was not possible to decide whether the duration of posttraumatic hemobilia was dependent upon the extent of traumatization.

- 10643 P-HYDROXYPROPIONPHENONE VS. CCl₄-INDUCED INJURY. (E.) Unakar, N. J. (Brown U., Providence, R. I.). Arch. Path. (Chicago) 82(2):170-177, 1966.

A total of 53 mice were given 3 different diets: laboratory chow (7 mice), control diet (22 mice) and experimental diet (24 mice). Control and experimental diets

identical except that experimental diet had 1% p-hydroxypropiophenone substituted for 1% of the starch contained in the control diet. All 53 mice were fed 2 or 3 times weekly with 0.1 ml of 40% CCl_4 and 60% olive oil. Most animals received a total of 54 doses CCl_4 ; only a few being sacrificed after fewer doses. All animals were maintained on laboratory chow after dose 54 of CCl_4 in order to study the progression of gross structural changes initiated by CCl_4 . All other animals were killed on the day following dose 54 for autopsy and for preparation of liver to be used in optical and electron microscopy. Ten additional mice (5 on control and 5 on experimental diet only) were used to demonstrate that the chemical itself had no effect on normal liver structure. Liver of mice receiving 25 or more doses of CCl_4 , irrespective of diet, showed swelling, granulation, changes in color and white patches. Seventy per cent of animals receiving 54 doses of CCl_4 , even the diet, developed hepatic nodules which grew longer in those animals transferred to laboratory chow. Histologically these nodules resembled hepatomas. This indicates that PHP did not inhibit CCl_4 induction of hepatomas in mice. Light microscopy: In animals receiving 35 or fewer doses of CCl_4 , 4 types of parenchymal cells could be recognized. (1) Cells, apparently unaffected, staining normally with a moderate amount of glycogen. (2) Finely vacuolated cells, diffuse basophilic staining, glycogen sparse or absent. (3) Classical balloon cells with coarsely vacuolated cytoplasm and a light, very diffuse material staining with methylene blue; glycogen very sparse or absent; nuclei often pyknotic or absent; (4) necrotic cells with deeply eosinophilic granules or amorphous cytoplasm and pyknotic or fragmented nuclei. In animals given 54 doses of CCl_4 hepatic cells seemed to become resistant to the chemical. Normal cells seemed to be abundant and distributed in groups especially around the portal vein. Balloon cells were infrequent and necrotic cells scarce. The presence or absence of p-hydroxypropiophenone in the diet made very little difference. Electron microscopy confirmed the findings of light microscopy. The microbodies in cells of CCl_4 -treated animals seemed more numerous. The mitochondria of all types of cells except the necrotic appeared normal in size and structure.

EFFECTS OF STARVATION ON THE HEPATOTOXICITY OF CARBON TETRACHLORIDE. A LIGHT AND ELECTRON MICROSCOPIC STUDY. (E.) Krishnan, N. (Western Reserve Univ., Cleveland, O.) and R. J. Stenger. *Am. J. Path.* 49(2):239-255, 1966. Male rats (150-220 g) were sacrificed following starvation for 72 hr. Groups of rats (150-260 g) were starved for 72 hr. and inj. s.c. with 0.5 ml of 50% CCl_4 in olive oil. Some of these rats were starved for further periods of 24, 30, and 36 hr. For comparison, rats on stock diet were given 0.5 ml CCl_4 s.c. and were sacrificed at the same intervals (2 animals at each interval). Comparable groups of rats maintained on stock diet or starved for 72 hr. were admin. 0.5 ml olive oil and similarly sacrificed. Animals were stunned by a sharp blow on the head or by which the neck vessels were severed. Tissue blocks were obtained from the right and left lobes of the liver in each animal. Paraffin sections were prepared for optical microscopy and for the electron microscope. (I) Optical microscopy: Starved rats fasted for 72 hr. exhibited moderate glycogen depletion, parenchymal cells seemed much smaller than normal and younger rats fasted for 72 hr. showed an almost depleted store of glycogen. Electron microscope: Glycogen depletion was more apparent as it was in the optical microscope; there was also a reduction in smooth endoplasmic reticulum (SER) and changes in rough endoplasmic reticulum (RER), i.e., enlarged mitochondria with increased number of cristae; in younger starved rats the number of lysosomes was increased. (Olive oil-treated rats were about the same as control controls.) (II) Optical microscopy: Inj. of CCl_4 after 24 hr. caused a centrilobular zone of pale cells containing small fat droplets to appear; little necrosis or inflammation was observed. Electron microscopy: The centrilobular pale zone at 24, 30, and 36 hr. showed moderate glycogen depletion and a generalized dilation of SER and RER. (III) Optical microscopy: In the starved group the hepatotoxic effect of CCl_4 seemed to be exaggerated. At the end of 24 hr., there was a centrilobular zone of pale eosinophilic preneurotic cells; there was a slight focal necrosis with mononuclear cell infiltration. At 30 hr. the zone was frankly necrotic and at 36 hr. there was centrilobular collapse. Electron microscopy: Three distinct cell types showing alterations were in the starved group: a) Hydropic

cells in the midzone; they had a generalized and severe dilatation of RER with dissociation of ribosomes whereas SER appeared almost normal; other organelles showed little or no change. b) The cells of the centrilobular zone were almost completely disorganized and degenerated. Necrotic parenchymal cells in the central zone at 36 hr. exhibited a total deterioration in cellular architecture.

- 10645 ACUTE TOXIC EFFECTS OF AFLATOXIN ON HUMAN EMBRYO LIVER CELLS IN CULTURE. (E.) Zuckerman, A. J. (London Sch. Hygiene Trop. Med., England) and F. Fulton. *Brit. Med. J.* 2(5505):90-91, 1966.

Implants of embryonic human liver tissue were made on polyethylene discs under aseptic conditions using Eagle's minimal essential medium with 0.15% bicarbonate and 10% fetal calf serum as control medium. This medium was made up with 2 conc. of aflatoxin B, 5 and 10 ppm as the experimental media on which also were floated polyethylene discs of human liver tissue. The implants were examined at varying intervals by fluorescence microscopy after staining with freshly prepared 1/1000 acridine orange. The first changes noticed in the cultures on the 10 ppm aflatoxin B medium after 3 hr. were an alteration in the normal granular appearance of RNA in the cytoplasm and a loss of definition of the nucleoli. After 16 hr. exposure, the overall cellular dimensions were reduced; the cells were rounded up and showed a complete loss of orange (RNA) fluorescence from the cytoplasm which was opaque and fluoresced a deep emerald green. The nucleoli could no longer be identified; chromatin which normally stains green was lost from the nucleus which assumed a deep opaque orange coloration. These changes became progressively more striking until death of the cell after 40-44 hr. At a conc. of 5 ppm of aflatoxin B no change occurred until 20-24 hr. exposure when the changes described above occurred very rapidly.

- 10646 EFFECT OF MANGANESE COMPOUNDS ON THE FAT CONTENT IN THE LIVER OF ANIMALS INTOXICATED WITH CARBON TETRACHLORIDE. (Uk.) Voinar, A. I. (Inst. Med. Donetsk, USSR) and V. N. Galakhova. *Ukr. Biokhim. Zhur.* 38(3):294-296, 1966.

In the liver of albino rats treated by carbon tetrachloride (CCl_4 ; 0.4 ml/100 g body wt./day for 4-5 days, s.c.) alone the amounts of total lipid (L = 13.0%) and phospholipids (P = 212 mg %) were markedly increased when compared to controls (L = 4.8% and P = 75.0 mg %, resp.). In the rats treated first by manganous chloride (MnCl_2 ; 0.7 mg/kg for 15 days, s.c.) and then by CCl_4 the total lipid content in the liver was lower (L = 11.6% and P = 203.0 mg %, resp.) than in rats not pretreated by MnCl_2 . MnCl_2 admin. after the intoxication with CCl_4 caused a quicker disappearance of fat deposition, markedly decreased its content (L = 4.1%) and decreased the amount of P in liver (P = 24.0 mg %).

- 10647 LESIONS ASSOCIATED WITH CLOSED LIVER INJURY. A CLINICAL STUDY OF 192 FATAL CASES. (E.) Hellstrom, G. (U. Uppsala, Sweden). *Acta Chir. Scan* 131(6):460-475, 1966.

Transcapsular liver rupture was studied in 192 fatal cases. The mean age was 8 y higher in 60 patients who died before admission (65 died within 12 hr.). The incidence of associated injuries other than fractures increased with age. Profuse hemorrhage occurred in 23 of 96 cases who died after admission with only liver rupture. Liver damage without clinical signs of other injuries occurred in 18 of the 192 cases. Seventy-two cases showed damage to skull and/or brain. In 45 of these the skull trauma occurred simultaneously with liver trauma. Thoracic injury was confined in 13 cases. Rib or sternal fractures occurred in 108 cases while 22 had intrathoracic injury without associated fractures. Cardiac rupture occurred in 17 cases. Partial endocardial rupture occurred in 3 cases with severe thoracic injury, while endocardial hemorrhage occurred in the left ventricle in 7 cases. Circulatory insufficiency existed in 39 cases, while 48 cases of aortic rupture, mostly below the aortic arch, were detected, of which 17 were combined with liver rupture and 11 were combined with rupture of both liver and spleen. Pulmonary damage occurred in 36 cases, all associated with thoracic bone injury. Pulmonary hemorrhage, subpleural, was seen in 20 cases, 15 without thoracic fractures. Associated intraabdominal injuries occurred in 70 cases with liver rupture, the

le intraabdominal lesion in 91 cases (31 cases were not examined). Splenic pture was the most common and was seen in 37 cases. Adrenal lesions were shown 17 cases and urogenital tract lesions in 14 cases. Diaphragmatic rupture curred in 16 cases and pancreatic rupture in 5 cases. Pelvic fractures occurred 41 cases and long bone fractures in another 41 cases. The latter was associated th fat emboli in 5 cases. Vertebral column fractures occurred in 6 cases. Signs aspiration were found in 6 cases. It was also noted that in 13 patients who ed prior to admission, no associated lethal injuries could be found.

- 648 PHENOTHIAZINE DERIVATIVES AND MORPHOLOGIC CHANGES IN THE LIVER. (E.) Hollister, L. E. (Veterans Admin. Hosp., Palo Alto, Cal.) and R. A. Hall. *Am. J. Psychiat.* 123(2):211-212, 1966.

he effect of chlorpromazine in modest doses over a comparatively short time upon ver histology was studied by comparing 25 liver biopsy specimens, from placebo-reated patients (who had never received a phenothiazine derivative) to 20 biopsy ecimens from patients of about the same age and sex recently treated with chlor-omazine. Identification of the liver tissue slides was masked; blind readings re made independently by 3 qualified readers. All 3 agreed in reading slides of of 20 patients on chlorpromazine and slides of 17 of the 25 controls. There s no significant difference in the frequency of abnormalities reported for the lorpromazine group and the control group. It is suggested that non-specific normalities of the liver are relatively frequent among chronically hospitalized ychiatric patients who have never been treated with antipsychotic drugs.

- 649 HEPATIC LIPID METABOLISM IN CARBON TETRACHLORIDE POISONING. INCORPORA-
TION OF PALMITATE-1-¹⁴C INTO LIPIDS OF THE LIVER AND OF THE d <1.020
SERUM LIPOPROTEIN. (E.) Weinstein, I. (Vanderbilt U. Sch. Med., Nash-
ville, Tenn.), G. Dishmon and M. Heimberg. *Biochem. Pharmacol.* 15(7):
851-861, 1966.

vers obtained from rats 3-5 hr. after treatment with CCl₄ (0.25 ml/100 g p.o.) e perfused *in vitro* for 3 hr. with rat serum containing C¹⁴-labeled palmitate. imitate incorporation into triglycerides and cholesterol was increased and the incorporation into phospholipids was decreased in the livers of treated rats. The lease of triglycerides, phospholipids and cholesterol into the low-density lipo-roteins was inhibited. It is suggested that the increased total triglycerides d the decreased triglyceride levels in the low-density lipoproteins may result om a depression of triglyceride release. Phospholipid metabolism may be de-essed both in the biosynthetic and the release stages by CCl₄. If the release triglycerides, phospholipids, and cholesterol takes place in a definite molar tio, then depression of the synthesis of 1 fraction will inhibit the release of e other 2 fractions.

- 650 EXPERIMENTAL AND CLINICAL STUDIES ON THE INTRAHEPATIC VASCULAR CHANGES
IN CHRONIC LIVER INJURY. I. MICROSCOPIC VITAL OBSERVATION OF THE
MOUSE LIVER IN CHRONIC CARBON-TETRACHLORIDE INTOXICATION. (E.) Tamao,
H. (Okayama U. Med. Sch., Japan). *Jap. Circ. J.* 30(3):205-216, 1966.

ver circulation was studied in mice treated with a 20% soln. of CCl₄ (0.1 ml/10 s.c. every 4 days) for up to 6 or 8 mo.; mice treated for 6 mo. were studied for gns of recovery. After 3-5 wk. of treatment, the sinusoids were tortuous with ough outlines; the central zone sinusoids seemed narrowed or obstructed, while ose at the periphery of the lobule were dilated with an increased blood flow. patic cell degeneration, spotty necrosis (especially in the centrolobular region), d foci of regeneration were seen. After 2 mo. of treatment, there were only 2-3 nusoids in each lobule. The open sinusoids were almost doubled in diameter, and re regarded as an early form of intralobular portohepatic shunt. Liver paren-ymal cells showed degenerative changes, with massive necrosis in the central ne but without conspicuous round cell infiltration or fibrosis. India ink rticles collected in the arteries and the enlarged sinusoids. Microscopic vital servation of mice treated for 3 mo. showed very few narrow open sinusoids with pid circulation, great dilation of the surface blood vessels and marked shrink-e of the central vein. Cellular necrosis was very extensive and round cell

infiltration into the lobule was seen. After 4 or 8 mo. of treatment the peripheral blood vessels were extensive, and necrotic cells were replaced by connective tissue while the central and interlobular veins were very irregular.

- 10651 INHIBITION OF INTESTINAL PROTEIN SYNTHESIS AND LIPID TRANSPORT BY ETHIONINE. (E.) Hyams, D. E. (Harvard Sch. Med., Boston, Mass.), S. M. Sabesin, N. J. Greenberger and K. J. Isselbacher. Biochim. Biophys. Acta 125(1):166-173, 1966.

In fasted rats, ethionine treatment (1 mg/g in 2 equal i.p. doses 1 hr. apart) caused a decrease in plasma triglycerides from 313.9 mg/100 ml (controls) to 33.5 mg/100 ml. Treatment with ATP (100 mg s.c., 0-7 hr. after ethionine treatment) did not modify this effect. Ethionine did not affect net absorption of triolein in isolated intestinal loops (75% and 77% of admin. dose in control and treated rats, resp.), but the transfer of labeled tripalmitin was decreased from 30.8% (controls) to 8.6%. Protein synthesis, measured by ^{14}C -L-leucine incorporation, was decreased about 45% in jejunal and liver tissue. ATP completely antagonized the effect of ethionine in the liver tissue, but enhanced its effect in jejunal tissue. Liver ATP levels decreased markedly and rapidly after ethionine treatment, but there was no significant decrease in intestinal ATP levels. The difference may be explained by the difference between the liver and jejunum in content of the methionine-activating enzyme (which is 6 times higher in the liver than in the jejunum). Histological and ultramicroscopic examination showed no significant changes with regard to triglyceride transfer through the intestinal mucosa.

- 10652 ACUTE TOXICITY OF AFLATOXIN B_1 IN THE DOG. (E.) Newberne, P. M. (Massachusetts Inst. Techn., Cambridge), R. Russo and G. N. Wogan. Path. Vet. (Basel) 3(4):331-340, 1966.

Normal dogs fed aflatoxin B_1 -contaminated commercial dog foods (1.75 ppm in 1 dog, 0.5 ppm in 2 dogs) showed minimal to moderate hepatic lesions upon sacrifice after 35 days. Similar toxic lesions were seen after 30 days of treatment with aflatoxin (0.1 mg/day); 1 dog given a higher dose died after 17 days of treatment with moderate hepatic lesions. Purified aflatoxin B_1 (0.2 mg/day x 15 days p.o.) caused no deaths up to 13 days after the end of treatment; the animal sacrificed at that time showed moderate to severe hepatic lesions, while another animal died 20 days after the end of treatment. When aflatoxin B_1 was admin. i.p. (1 mg/kg), 67% of the animals died within 2 wk. When the same dose was admin. in 2 doses at a 4-day interval, the dogs that survived for 9 days (67% of the treated group) and were sacrificed at that time showed moderate to severe hepatic lesions. In all treated groups, clinical signs of toxicity consisted of anorexia, wt. loss and jaundice. Small repeated doses of aflatoxin were therefore less toxic than single larger doses; aflatoxin was of essentially equal toxicity after p.o. and i.p. admin. The lethal doses of aflatoxin in dogs were within the same range reported for ducks, guinea pigs, and rabbits. The liver lesions resembled those of hepatitis X, with fatty changes, bile duct hyperplasia, severe congestion, centrilobular parenchymal necrosis, and yellowish discoloration of the liver. Other findings included icterus of the serous and mucous membranes, gallbladder edema, ascites, and occasional hemorrhage into the intestine. Acute poisoning resulted in congestion and hemorrhage of the adrenal cortex.

- 10653 THE EFFECTS OF AFLATOXIN B_1 ON THE PREGNANT RAT. (E.) Butler, W. H. (Univ. Coll. Hosp. Sch. Med., London) and J. S. Wigglesworth. Brit. J. Clin. Path. 47(3):242-247, 1966.

When aflatoxin B_1 was admin. to rats in late pregnancy (at 25% of LD_{50} for non-pregnant rats), fetal growth retardation was seen and maternal liver injury was greater than seen in normal rats or in rats in early pregnancy. The latter 2 groups were affected in the same way; no fetal wt. loss was seen after early treatment. When aflatoxin was admin. on day 16 of pregnancy, on day 21 the adults presented congested fatty livers with far more necrosis, fatty infiltration, and biliary proliferation than seen at this time interval in either non-pregnant rats or rats treated in early pregnancy. Fetuses from rats treated in late pregnancy showed significant wt. loss, compared to fetuses from rats which were treated in the early

ages of pregnancy; the degree of growth retardation seemed to be correlated with the extent of maternal liver damage. The placenta was not damaged in any case, so that the growth retardation seemed to be secondary to maternal liver damage caused by aflatoxin B₁.

- 554 EFFECTS OF RADIATION ON THE LIPID COMPOSITION OF THE SERUM AND THE LIVER OF THE RAT. (It.) Angelico, R., G. Casparrini, G. Cavina, L. Moretta Maggiore and M. Quintiliani. Ann. Ist. Super. Sanit. 1(11-12):698-707, 1965.

Male Long-Evans rats (fasted for 12 hr.) received 100 r whole body irradiation and sacrificed 48 or 72 hr. later. Total lipids were extracted with chloroform-methanol procedures from pools of equal amounts of serum or homogenated liver collected from 3-5 rats, 7 experimental and 4 control pools being used for each of the 2 time periods; lipid components were separated by thin layer chromatography. Significant increase in total serum lipids was observed either 48 hr. (+47.8 mg/100 ml over controls) or 72 hr. (+64.1 mg/100 ml over controls) after irradiation, whereas liver lipids showed minimal changes (-5.0 mg/g liver and -6.2 mg/g, resp.). The hyperlipemia was mainly due to free and esterified cholesterol, phospholipids, and triglycerides, which increased proportionately to the increase in total lipids; glycerides and free fatty acids showed only minimal changes. Decreases in cholesterol (free and esterified) and triglycerides occurred in the liver. Gas chromatographic analysis of the composition of free fatty acids 48 hr. after irradiation showed no significant difference from control values.

- 555 THE ACTIVITY OF GLUTAMIC-OXALACETIC AND GLUTAMIC-PYRUVIC TRANSAMINASES (GOT AND GPT), ORNITHINE-CARBAMOYLTRANSFERASE (OCT) AND ALKALINE PHOSPHATASE (AP) IN SERUM IN CLOSED LIVER INJURY. AN EXPERIMENTAL STUDY IN DOGS. (E.) Hellstrom, G. (U. Uppsala, Sweden). Acta Chir. Scand. 131(6): 476-484, 1966.

Dogs submitted to closed liver injury exhibited an increase of glutamic-oxalacetic (GOT) and glutamic-pyruvic transaminase (GPT) activity above the normal value immediately after trauma. The amount of the increase generally corresponded to the severity of the trauma, occurring immediately after the injury. In 5 of 9 dogs studied, ornithine-carbamyl transferase (OCT) activity also rose after liver trauma, but with 2 dogs this increase remained within the upper limits of normal. In no case did the alkaline phosphatase activity increase above the normal limit. The liver injury was produced by a weight of 15.5 kg dropped in pendulum fashion on the right side half-way between the xiphoid process and umbilicus. The same trauma applied to a muscle did not produce these enzymatic changes. These data would indicate that elevated values for GOT, GPT, and particularly OCT (which is a liver-specific enzyme) would add to any suspicion of liver rupture.

- 556 NUTRITIONAL HEPATIC NECROSIS IN BEEF CATTLE: "SAWDUST LIVER". (E.) Toss, G. C. (New York State U. Vet. Med., Ithaca) and L. Krood. Path. Vet. (Basel) 3(4):379-400, 1966.

Histological examination of 21 spontaneous cases of "sawdust" livers in cattle indicated that this focal liver necrosis was an expression of vitamin E-selenium deficiency. When cattle were experimentally placed on a diet low in vitamin E, protein, and selenium, all developed "sawdust" livers. Partial protection against liver degeneration was provided by treatment with sodium selenite (20 mg s.c. every 35 days) or soybean oil meal (0.23 kg/animal/day). Microscopic examination showed that the earliest lesions were in the liver cord cells, appearing as granular globular hyalinization of the cytoplasm. Eventually large hyaline bodies were found in the cytoplasm. This type of lesion was not restricted to the liver, but was also found in the heart, kidney, and skeletal muscle. Pyloric lesions, however, consisted of gradual loss of epithelium with a denuded, often hemorrhagic submucosa. Plasma glutamic-oxalacetic transaminase or ornithine carbamyl transferase did not change significantly in this nutritional hepatic necrosis.

- 557 SIGNIFICANCE OF SERUM PROTEIN ABNORMALITIES ON THE MECHANISM OF EXPERIMENTAL HEPATIC REGENERATION. (It.) Bazzicalupo, G. (U. Parma, Italy),

G. Bellodi, C. Carnevali and P. Pietranera. Minerva Med. 57(13):496-500, 1966.

Total serum proteins, hepatic mitotic index, and liver wt. increase were determined 30-50 hr. after 65% hepatectomy in rats. Postoperatively, Group I (15 rats) was given 10 ml of physiological solution s.c. and Group II (36 rats) was given 10 ml of 5% glucose s.c. At the time of surgery in Group III (22 rats), 6-8 ml of blood was exchanged for blood in which Ringers' solution had been substituted for the plasma fraction; these rats also received 10 ml of 5% glucose postoperatively. A fourth group of controls (20 rats) was subjected to the plasmapheresis only and sacrificed after 5, 24, 36, or 46 hr. Statistical analysis of the data revealed a significantly higher mitotic index in Group II as compared to either Group I or III. Controls showed no appearance of mitotic activity. Serum proteins returned to basal values within 24 hr. of controls, but in hepatectomized animals they remained low for at least 46 hr., being most depressed in Group III. A comparison of hepatic wt. increase and mitotic index in Groups I, II, and III led to the conclusion that dysproteinemia has a marked inhibitory effect on both indices of the regenerating liver, the livers of dysproteinemic rats being unable to avail themselves of glucose. It is suggested that hypoproteinemia causes disturbances in the transport of steroids and especially of thyroid hormones, and reduced synthesis of protein hormones, systemic enzymes, and cellular constituents, resulting in an insufficient supply of essential amino acids to the liver.

- 10677 THE NATURE OF Macacus rhesus ERYTHROCYTE AGGLUTININS FOUND IN THE SERA OF HEPATITIS PATIENTS. (E.) Kaito, I. (Tohoku U. Sch. Med., Sendai, Japan), S.-I. Sato, M. Sanada, N. Matsuda, R. Ohta-Hatano, H. Tozawa, Y. Hinuma and N. Ishida. Proc. Soc. Exp. Biol. Med. 122(3):850-856, 1966.

Agglutinin titers for Macacus rhesus RBC were higher in sera from 64 patients with infectious hepatitis than in sera from normal persons. In addition, approx. 88% of the patients had measurable titers as opposed to 65% of the controls. Ultracentrifugation, zone electrophoresis, gel-filtration and tests of heat sensitivity and mercaptoethanol inactivation demonstrated that this agglutinating component is a macroglobulin 19 S antibody. Hemagglutination titers were the same when the RBC serum mixture was incubated at 4°C, 20°C, and 37°C, but the agglutinin could be removed by adding packed RBC which indicates that the hemagglutinin is antibody rather than viral.

- 10678 URINARY ESTROGEN DETERMINATIONS AFTER HEPATITIS. (Hun.) Székessi, J. Orv. Hetil. 107(22):1022-1024, 1966.

Twenty female patients, ages 23-37 yr., with a history of hepatitis within 3 yr. prior to this study were tested for urinary estrogen levels; the specimens were taken 10-12 days after start of the cycle. Fifteen patients had residual symptoms attributable to the previous condition (hepatitis) but only 10 of 15 had objective symptoms. In addition, 8 patients had gynecologic disturbances of various etiology. Eight of the 20 patients had significantly higher total estrogen values (between 52-162 µg). Highest normal av. value: 40 µg.; 6 of these 8 had gynecologic complaints; also 6 of 8 had posthepatic symptomatology. The total hormone increase was mainly due to elevated estrone levels (31-70 µg as against the upper normal average limit of 16 µg). A statistical correlation was found to exist between residual hepatic symptomatology and total estrogen levels and between hepatitis symptoms and estrone levels. It is concluded that urinary estrogen determinations may be useful in following the course of posthepatic developments.

- 10679 TUBERCULOSIS AND CHRONIC HEPATITIS SECONDARY TO EPIDEMIC HEPATITIS. (Rum.) Gherman, G (Inst. Path. Anat., Bucharest), A Centea, E. Paian, T. Lungu, I. Perta and V. V Papilian. Med. Intern. (Bucur.) 18(5):553-566, 1966.

An extensive clinical, biochemical and histologic study of 50 patients with pulmonary tuberculosis (TB) and a history of infectious hepatitis was made to determine the factors contributing to chronicity of the hepatic condition. Patients were in various levels of drug therapy (totals: streptomycin from 2.0-100 g; isonitric acid hydrazide 1,000 to over 5,000 tablets; paraaminosalicylic acid 10-300 perfusions plus tablets; Nizotin 30 to over 300 tablets.), representing one mo. to 15 yr. of treatment. Liver diagnoses (% positives of biochemical and histologic tests are given in the text) range from 17 patients (34%) with normal liver functions; one patient with fatty liver; 31 patients (62%) with chronic hepatitis (14 of 31 stabilized and 17 of 31 evolutive, and one patient with hepatic cirrhosis). The results indicate that duration of the patients is a factor in enhancing chronic transformation, i.e. 41% of patients with normal liver function had TB for less than 1 yr.; this decreased to 23.5% with TB of over 5 yr. duration. In patients with chronic hepatitis, TB of 1 yr. duration existed in 24.4% and TB of over 5 yr. in 36%. Stabilized chronic hepatitis associated with TB of 1 yr duration was 21.2%, with TB of over 5 yr. 28.5%, while the figures for association with evolutive chronic hepatitis are 23.5% and 41.5%, resp. The extent of existing pulmonary lesions seems to have no influence in the progression of liver pathology; no interrelationship seems to exist between pulmonary and liver lesions either. In 30 patients (60%), TB preceded infectious hepatitis by one mo. to 15 yr. Where liver function was normal, the frequency of either disease having appeared first, was approx. equal; however, in 66% of patients found with liver damage, TB was the first disease. If one considers the evolutive conditions alone, TB appeared first in 70.5% of such patients. The duration and the intensity of TB therapy seems to have no

fect on development of chronicity, although evolutive conditions seem slightly re frequent in patients who have received massive anti-TB drug therapy (statistically insignificant). Evolution towards chronicity seems more rapid (but otherwise identical) in patients with TB than without TB. An indirect enhancing influence of TB on chronic evolution may also be inferred from the fact that in % of the existing chronic cases the infection was transmitted via inj.; considering the evolutive cases only, the % inoculation infection becomes 76.5%, suggesting that infectious hepatitis acquired through therapy of any kind is more prone to evolution towards chronicity.

680 TRANSFUSION-ASSOCIATED VIRAL HEPATITIS. (E.) Mosley, J. W. (Communicable Dis. Ctr., Atlanta, Ga.) and H. B. Dull. Anesthesiology 27(4):409-416, 1966.

ata are presented about the onset of symptoms collected from 718 persons who received their transfusions all in one 24-hr. period. The incubation periods in these 718 cases extended from 15-180 days; 250 individuals (34.8%) had incubation times from 15-50 days; the curve of incubation periods appears to be unimodal with a peak (54 cases) occurring between days 45 and 50. A classification of human blood and blood derivatives according to risk in transmitting viral hepatitis is given. "Average risk" materials are: whole blood, fresh or stored, packed RBC, single donor plasma, platelet-rich plasma, fresh frozen plasma. "High risk" derivatives include irradiated pooled plasma, pooled plasma stored at room temperature for 6 mo., fibrinogen, antihemophilic globulin. "Safe" derivatives (pooled, adequately treated) are: plasma stored at 31.6° C for 6 mo. (evaluation required) and those chemical extractives such as serum albumin, plasma protein fraction, etc. An effective method for sterilizing fibrinogen or antihemophilic globulin preparations is now available. Several possible approaches to the problem of prevention are discussed. The use of immune globulin where there is risk of viral hepatitis from transfused materials is considered.

681 THE VALUE OF THE COLLOIDAL RED AND OF THE CHLORANILIC ACID TESTS IN THE DIAGNOSIS OF ACUTE AND OF CHRONIC HEPATITIS. (Rum.) Ceasi, E. (City Hosp., Turnu-Severin, Rumania), V. Torjescu, D. Pirvu and M. Valeanu. Med. Intern. (Bucur.) 18(5):595-599, 1966.

The authors analyze the diagnostic value of the colloidal red (CRT) and of the chloranilic acid (CAT) test performed on 371 patients and 38 healthy adults. There were 238 cases of epidemic hepatitis in various clinical forms, 67 chronic hepatitis cases, 18 cirrhotoses, 7 hepatic and pancreatic neoplasias, 3 cholelithiasis, 6 cases of angiocholitis, and 32 cases of other gastrointestinal pathology. CRT was positive in 156 of 305 infectious hepatitis cases (58%) and CAT in 191 of 305 cases (62%). There was an 84% correlation between the 2 tests, with the 16% discrepancy being "moderate." In most cases of chronic hepatitis both tests were positive to intensely positive (CRT: 64/67; CAT: 61/67), and in hepatic cirrhosis both were intensely positive (18/18). No changes in the results were seen during evolution of the disease; only in 9 cases did they become positive during the recovery period. In the patients, these having been interpreted as signs of evolution towards chronicity. There is no variation in results due to the various clinical forms of hepatitis, but this is true only for the first few weeks of the disease. A definite discrepancy has been observed between the CRT-CAT results and the results of tests for dysproteinemia, the latter being mostly positive (moderately, or intensely), both in the initial (acute) and in the evolutive stages of the disease. Finally, there is an inverse correlation between CRT-CAT results and serum enzyme levels, the latter being elevated in the initial stages, and normalized or decreased as the condition progresses towards chronicity or cirrhosis. Both tests are highly recommended for their accuracy and ease of performance, especially in mass studies.

682 NATURAL IMMUNITY FACTORS IN THE COURSE OF VIRAL HEPATITIS. (It.) Teti, M. (Catholic U., Rome, Italy). Minerva Med. 57(36):1602-1603, 1966.

The mechanisms of action which can explain the intense and protracted reduction of lysozyme (accompanied by transitory reduction of properdin) in viral infection are proposed. Lysozyme possesses great affinity for polyanionic radicals, from which

it liberates properdin (the labile bond explaining the transitory drop in properdin) to form more stable complexes with them. According to this concept, the action of properdin would be to assure the immediate entrapment and subsequent transport of the "polysides" and virus; that of lysozyme would be as part of control mechanisms operating at a distance from the infection. When added to homogenates of infected mouse livers, lysozyme causes flocculation; the precipitate, after centrifugation, contains almost all of the viral infective units. This is due to the adsorption of the viral particles, which retain their infective capacity, on the insoluble complexes formed between the basic colloid and polyanionic substances. Thus they can be split from liver cells to become an easier prey for tissue macrophages. This was demonstrated first with myxovirus anchored to complexes formed by lysozyme with Rivalta-positive substances produced in embryonic tissues of infected chickens, and then with murine liver virus EHF 120 in mice. Subsequently, another author (Kubelka) has obtained similar results with other viruses, including Praga-Motol, isolated from cases of human hepatitis. The author will also report experimental results which show that lysozyme can notably decrease the phlogistic-necrotic action of virus EHF 120 in the mouse liver and can improve the energy metabolism of the infected organ by forming electrostatically inert complexes with acid substances.

- 10683 AGE PECULIARITIES AND FOCAL NATURE IN EPIDEMIC HEPATITIS ACCORDING TO DATA OF THE MOSCOW REGION. (Rus.) Spotarenko, S. S. (Sechenov 1st Moscow Med. Inst., USSR). *Sovet. Med.* 29(4):94-97, 1966.

The incidence of epidemic hepatitis among children in the Moscow District in 1959-62 is analyzed in terms of the children's age and environment. Among those 2 yr. old or less, the morbidity was 4-10.8 times higher in those who lived in an "organized" setting (i.e., in crèches), and 1.5-3.1 times higher in those 3-6 yr. old attending nursery school or kindergarten, than in "unorganized" children. Children under 16 yr. of age were 6.5 times more apt to infect family contacts than were those over 16, and contacts under 16 were far more apt to contract the disease than were those over 16. The observed differences in the epidemiologic hazard presented by and to the different age groups and under different living conditions can be explained, in part, by the relatively more intimate contacts among smaller children and by the improvement in health habits that comes with increasing maturity, as well as by the specific immunologic characteristics of particular age groups.

- 10684 MASS SMALLPOX VACCINATIONS IN POLAND IN THE SECOND HALF OF 1963 AND THE EPIDEMIC SITUATION OF VIRAL HEPATITIS. (Pol.) Kulesza, A. (Cent. Hosp., Warsaw, Poland), M. Kacprzak and L. Milewska. *Przegl. Epidem.* 19(3):321-330, 1965.

After 1951, when registration of the disease was initiated, the incidence of viral hepatitis in Poland increased steadily, reaching epidemic proportions in 1959 (260 per 100,000 inhabitants) and again in 1963. The number of cases began its sharp rise in July of that year, and in the fourth quarter, the coefficient of morbidity in various parts of Poland ranged from 500-700/100,000. In July-September of this same year, after an outbreak of smallpox in Wrocław, mass smallpox vaccinations were given. The percentage of the population vaccinated in various regions ranged from 4-100%. The incidence of viral hepatitis was especially high in those provinces and cities where the largest proportion (34-100%) of the population had been vaccinated, but it was equally high in other locales where only 7-9% had been vaccinated. Since the number of fourth-quarter cases of viral hepatitis in Poland as a whole was approx. 35,000 and the number of persons vaccinated over 8,000,000, it was not feasible to conduct an epidemiologic analysis on the whole country. Instead the province of Łódź, where the number vaccinated and the incidence of hepatitis most closely resembled the figures for Poland as a whole, was selected as a suitable model. Statistical analysis of the data from Łódź for Aug. 10, 1963 to March 8, 1964 indicated that, while the mass smallpox vaccinations were not responsible for the Polish hepatitis epidemic of 1963-4, and parenteral infection could have played only a minor role in its spread, smallpox vaccination may have increased the risk of hepatitis among vaccinees. This risk was apparently greatest 80-90 days after

initiation of the vaccination program, a period which coincides with the incubation period for serum hepatitis postulated by the World Health Organization.

- 685 IRON METABOLISM IN INFECTIOUS HEPATITIS. (Ger.) Burger, T. (U. Pecs, Hungary), K. Barna, B. Keszthelyi and J. Rauth. Zschr. Inn. Med. 21(12): 368-372, 1966.
- Iron metabolism was studied in 38 patients divided into 2 groups, 21 with acute infectious hepatitis (Group I) and 15 who were recovering from hepatitis (Group II) as well as 2 patients in hepatic coma. All patients were treated with $\text{Fe}^{59}\text{Cl}_3$ (20 mc). Serum iron values were generally increased, but an extremely high value (241 $\mu\text{g}\%$, compared to a normal value of 105) was found only in one case in Group I; the same group contained also one patient with normal serum iron. In Group II, 6 of 15 had normal serum iron levels. Plasma iron clearance was accelerated in 16 of 21, and normal in 5 in Group I; it was accelerated in 2 of 15, normal in 13 and slow in 2 in Group II. Plasma iron turnover/24 hr. in Group I was increased in 18 and normal in 3. In Group II, it was increased in 3 of 15, normal in 9, and decreased in 3. RBC iron turnover (incorporation/24 hr.) was elevated in 17 of 21, normal in 4 in Group I; in Group II it was elevated in 1, normal in 8 and slightly decreased in 6 of 15. Values in the 2 patients in hepatic coma were essentially normal. The differences between the two groups were significant ($p = 0.01$). The av. RBC life span (Cr^{51}) in the above patients was 15-24 days. No increases in the erythropoietic index were found only in 7 patients in Group I. In the absence of marked erythropoiesis, the increased iron metabolism cannot be explained by hemolytic processes alone. Measurements of radioactivity distribution curves showed that in contrast to normal subjects where bone marrow distribution was highest in the first 2-4 days, in 16 of 21 cases (Group I) and 9 of 15 cases in Group II, the highest counts were obtained over the hepatic area. This indicated the presence of labile iron deposits from the damaged liver parenchyma, which was also reflected by a higher and more prolonged plasma activity in hepatitis patients, which showed a direct correlation with the course of the disease. Despite sometimes severe iron metabolic disturbances in such cases, labile iron stores in the bone marrow seemed to be normal. No explanation is given for the normal values found in the 2 patients in hepatic coma.

- 686 HISTOPATHOLOGICAL FINDINGS IN ANIMAL EXPERIMENTAL ON THE AETIOLOGY OF VIRAL HEPATITIS. (E.) Baló, J. (U. Budapest Sch. Med., Hungary), G. Kendrey, M. Sellyei and A. Bajtai. Acta Microbiol. Acad. Sci. Hung. 12(4):357-361, 1965-1966.
- Histopathological changes were revealed in the livers of rats fed an ethionine diet, whether they were afterwards infected with human hepatitis virus or not. The most significant changes seen in both cases were proliferation of the bile capillaries and enlargement of nuclei and nucleoli of the hepatic cells. When livers from ethionine-treated infected rats were compared histologically with livers obtained from patients or dogs with infectious hepatitis, several significant differences were evident: no inclusion bodies were found; necrosis was seen only occasionally, and signs of inflammation were present. There was no difference between ethionine-treated and ethionine-treated infected rats which would indicate a specific effect exerted by hepatitis virus. Furthermore, there was no pathological change in the livers of infected and control rats which received a normal synthetic diet.

- 687 EXPERIMENTAL INFECTIOUS CANINE HEPATITIS. II. EFFECT OF CORTISONE ACETATE ON EXPERIMENTAL INFECTION IN THE GUINEA-PIG. (E.) Wright, N. G. (U. Glasgow, Scotland). J. Comp. Path. 76(3):297-301, 1966.
- Fatal effects of canine infectious hepatitis virus infection in guinea pigs were enhanced by cortisone acetate (12.5 mg i.m., 2 hr. before virus infection); none of the cortisone-treated animals survived more than 3 days following infection, whereas only 12 of the 27 animals not receiving cortisone died by day 3; 8 of them developed neurological symptoms 6-12 hr. before death, compared to 19 of the 30 cortisone-treated guinea pigs. In both groups, inclusions and virus antigen were most prominent in the vascular endothelium of the central nervous system, but they

were not observed in the neuronal or glial cells. Hepatic necrosis was not seen in either group. It was concluded that the enhancement of experimental canine infectious hepatitis virus infection in guinea pigs by cortisone occurs too rapidly to be due to depressed antibody response.

- 10688 ANIMAL EXPERIMENTS CONCERNING THE AETIOLOGY OF VIRAL HEPATITIS. (E.) Nagylucskay, S. (U. Budapest Sch. Med., Hungary), L. Sujbert, G. Szel, D. Tapfer and I. Vedres. Acta Microbiol. Acad. Sci. Hung. 12(4):351-356, 1965-1966.

The mortality rate for Leptospira- and Bartonella-free rats fed a methionine-deficient diet with 0.3% ethionine and subsequently infected p.o. or parenterally with human hepatitis virus was over 50% and 75%, resp. Rats receiving only ethionine showed a 50% mortality rate. Jaundice occurred in 33% of the ethionine-fed controls, somewhat more frequently in the p.o. infected group, and in approx. 75% of the animals infected parenterally. A significant increase in the relative level of γ -globulin and in the hemagglutinating capacity of the serum (measured in eggs) was demonstrated in ethionine-treated infected rats. However, the hemagglutinating agent was recovered from the liver extract of 2 rats which were neither infected nor on a special diet.

- 10689 ARTERIOSPASM AFTER ERGOTAMINE TARTRATE IN INFECTIOUS HEPATITIS. (E.) Katz, A. I. (Beilinson Hosp., Petah Tikva, Israel) and S. G. Massry. Arch. Intern. Med. (Chicago) 118(1):62-63, 1966.

A woman (9-mo. pregnant) was admitted with suspected infectious hepatitis and gave birth to a healthy infant after an uneventful labor. For 5 days after delivery, ergotamine tartrate (1 mg/d p.o.) was admin. for delayed uterine involution. During this period a progressive increase in jaundice was noted and the patient began to complain of paresthesias and painful sensation of cold in both feet; the pulse was absent in the feet, legs, thighs, lower and upper forearms. Limb ischemia worsened until 6 days after the discontinuation of ergotamine treatment when improvement finally became apparent. A few days afterwards, symptomatic improvement of the hepatitis was evident and the patient was soon released free of symptoms. It is concluded that arteriospasm can be caused by ergotamine, even in safe p.o. doses, in the presence of infectious hepatitis, since the liver is the principal site of detoxification of this drug.

- 10690 SERUM HEPATITIS AT THE VETERANS ADMINISTRATION RESEARCH HOSPITAL, CHICAGO 1954-1963. (E.) Laureta, H. C. (Northwestern U. Sch. Med., Chicago, Ill.), M. Vidinli and E. C. Texter. Gastroenterologia (Basel) 105(5): 257-269, 1966.

During the period 1954-1962, out of a total of 2182 units of commercial blood transfused to 5599 patients of whom most were over 40 yr. of age, the incidence for diagnosed serum hepatitis was 0.89%. Of these patients, 3 deaths resulted from the serum hepatitis, giving a mortality rate of 0.05%. The case fatality rate was 6%. Of the remaining patients with serum hepatitis, 26 recovered (2 did have relapses), 21 were recovered when last seen (1 had an intercurrent relapse) and 10 patients still had abnormal liver function tests for periods ranging from 4 mo. to over 1 yr. The most frequent abnormalities were retention of sulfobromophthalein and an elevated thymol turbidity. It was possible to determine the incubation period with certainty in 39 cases: it ranged from 28-159 days, with a median of 68 days. These results were compared with other hospital reports in Chicago, Cincinnati, Boston, Baltimore and Los Angeles and the differences in the epidemiologic aspects are discussed.

- 10706 INFLUENCE OF TESTOSTERONE TREATMENT IN EXPERIMENTAL NUTRITIONAL HEPATIC CIRRHOSIS IN THE RAT. (E.) Bengmark, S. (U. Göteborg, Gothenburg, Sweden), P.-H. Ekdahl, A. Gottfries, H. Mobacken, R. Olsson, B. Rehnström and T. Scherstén. Gastroenterologia (Basel) 105(5):301-315, 1966.

The i.m. admin. of 8 mg testosterone-3(p-hexyloxyphenyl)-propionate every third wk. for 5 mo. to male Sprague-Dawley rats which had nutritional hepatic cirrhosis (induced by choline-deficient diet for 8 mo.) did not benefit the animals' condition. Neither the histological picture, liver nitrogen nucleic acid and hydroxyproline conc., liver transaminase activity, liver capacity to synthesize tauro- and glycocholic acid in vitro nor serum protein fractions were significantly altered by this testosterone treatment. On a weight basis, the testosterone doses were comparable to those admin. in clinical studies.

- 10707 OBSERVATIONS ON PORTAL CIRRHOSIS FATALITIES. (E.) Palmer, E. D. (New Jersey Coll. Med., East Orange). Milit. Med. 13(7):588-592, 1966.

Of 216 patients with histologically proved portal cirrhosis not treated by portal decompression, 182 (84%) died as a result of their liver disease. Liver failure was the immediate cause of death in 143 (78.6%) of the 182 patients. In 85 of these, hepatic failure was initiated by hemorrhage, making a total of 112 deaths due to upper gastrointestinal hemorrhage, of which 24 were due to exsanguination from varices. Upon initial examination, 160 of the 182 patients had esophageal varices by endoscopy, and at the time of death only 62 had never bled. Thus 93.3% (112) of the patients who bled (120) died of bleeding; 73% of these had never bled prior to the terminal episode. Only 52.4% of 147 patients were still alive one year after a diagnostic liver biopsy was taken. Only 16.4% of 134 patients were alive 1 yr. after endoscopic demonstration of esophageal varices, and only 14.2% of the 120 bleeders were alive 1 yr. after the first recognized upper gastrointestinal hemorrhage.

- 10708 GASTRIC SECRETION IN CIRRHOTICS AFTER PORTASYSTEMIC SHUNTS. (It.) Ferrarese, S. (U. Bari, Italy) and V. Ronzini. Gazz. Int. Med. Chir. 71(10):882-889, 1966.

The gastric secretion (total and free acid) after max. histamine secretion (method according to Kay) was studied in 20 patients with histologically-proven hepatic cirrhosis before and after surgical intervention. Group 1 (10 patients) were not subjected to shunting procedures. No change in the secretory activity of 6 pre-operatively hypochlorhydric patients was found after splenectomy or ligation of the splenic or hepatic artery. Postoperative values were increased following splenic artery ligation and neurectomy of the hepatic artery or exploratory laparotomy in 2 patients with previously normal gastric acid, and were markedly decreased in 2 previously hyperchlorhydric patients subjected to vagotomy and hemigastrectomy or gastric resection for peptic ulcer. Group 2 (10 patients, all hypochlorhydric except one) had portal hypertension of 32-45 cm water and were subjected to shunting procedures. Of 7 patients with portacaval shunts, marked increase in secretion occurred postoperatively in 2, moderate increase in 4, and decrease in one. Two patients with spleno-renal shunts had no significant change, and 1 had a slight increase in secretion. In 4 of 5 of the Group 2 patients who were followed for 3-8 mo., gastric secretion remained elevated; none of these had symptomatic or X-ray evidence of peptic ulcer. Various hypotheses as to the pathogenesis of hypochlorhydria in hepatic cirrhosis and the change in secretory activity after portasystemic shunts are presented. In the latter case, the authors favor Ostrow's theory that improved gastric circulation is the basis for the increased secretion.

- 10709 SURGICAL TREATMENT OF INTRACTABLE CIRRHOTIC ASCITES. (E.) Orloff, M. J. Curr. Probl. Surg. 1966:28-51.

A large series of experiments on dogs is presented showing the effect of block of the hepatic veins in producing (1) ascites, (2) greatly increased hepatic lymph flow overwhelming the hepatic lymph vessels, (3) concomitant very large rise in the

release of aldosterone from the adrenal cortex and elevated blood conc. of the hormone. In dogs with side-to-side portacaval shunt complete obstruction of the hepatic veins did not produce ascites. When the portacaval shunt was taken down in 9 of the 9 dogs in this group, they promptly became ascitic with portal hypertension and hepatomegaly. In another group of dogs the hepatic veins were ligated, which invariably caused cirrhosis, portal hypertension, and intractable ascites. Side-to-side portacaval shunts resulted in recovery from ascites in 14 of 16 dogs. In 1 of 2 dogs with return of ascitic fluid, there was thrombosis of the shunt. In 10 hospital patients, who had received intensive medical treatment for ascites for 22 mo. including rigorous salt restriction, the gamut of diuretics and aldosterone antagonists, failed to respond to the regimen. Hepatic function tests indicated that they were all cirrhotic; however, none was jaundiced, and all except 1 had a serum albumin conc. of 3 g% or more. Side-to-side portacaval shunt was accomplished in 8 patients; 1 died in surgery. All had high portal pressure prior to the operation indicating severe outflow block. The 8 surviving patients had a dramatic postoperative diuresis; Na excretion rapidly reached normal levels. The patients have now been followed for 12-40 mo.; all were free of ascites when last seen and all had made sizable nutritional gains. All except 1 had slight-to-moderate improvement in liver function.

710 ACID MUCOPOLYSACCHARIDES AND CIRRHOSIS OF THE LIVER. (E.) Galambos, J. T. (Emory U. Sch. Med., Atlanta, Ga.). Gastroenterology 51(1):65-74, 1966.

The grading of human livers in terms of histochemically demonstrable mucopolysaccharides (MPS) was undertaken in 666 patients, of whom 109 had normal livers and 557 suffered from a wide diversity of hepatic disorders. Adequate liver samples were obtained from all of these patients to investigate the relationship between the amount of MPS (from the ground substance of connective tissue) and the clinical course of the patients. In samples of 30 additional postmortem livers there was a good correlation between the histochemical grading and the μg hexosamine (derived from the MPS fraction)/100 mg lyophilized defatted liver. The accumulation of histochemically demonstrable MPS (a) in the perisinusoidal space along parenchymal cells, (b) at the septal parenchymal junction, and (c) in areas of necrosis, was found to be associated with active fibrosis. When acid MPS accumulate in areas of injury without infiltration into the lobular parenchyma, and before the development of collagen bundles, the mesenchymal reaction may still be reversible. Those types of hepatic lesions, not associated with accumulation of MPS, were not followed by fibrosis and cirrhosis.

711 MEDIUM AND LONG CHAIN FAT ABSORPTION IN PATIENTS WITH CIRRHOSIS. (E.) Linscheer, W. G. (Tufts U. Sch. Med., Boston, Mass.), J. F. Patterson, E. W. Moore, R. J. Clermont, S. J. Robins and T. C. Chalmers. J. Clin. Invest. 45(8):1317-1325, 1966.

A general study of fat absorption was carried out on a total of 56 patients, 6 normal controls and 50 cirrhotic patients of whom 9 had undergone portacaval shunt operation. Fat balance studies involving long chain triglycerides (LCT) were made in 10 control subjects and 35 cirrhotic subjects (mean fecal fat $10.5 \pm 2.6\%$), and in 10 cases of portacaval shunt (mean fecal fat $7.7 \pm 2.1\%$); mean fecal fat in controls was 2.7%. Ten patients with cirrhosis and steatorrhea on alternating diets, one containing LCT and the other MCT (medium chain triglycerides, mainly octanoic triglyceride) had mean fecal fat of 24.2% and 7.4%, resp. Absorption studies in the upper small intestine were made with the 4-lumen 2 balloon tube method, the efficiency of which was proved by recovery of $93.6\% \pm 5.85$ polyethylene glycol (PEG) in infusate in 77 infusion trials. Sodium taurocholate in the infusions remained a constant ratio to PEG indicating that taurocholate is not absorbed in this portion of the intestine (from below the bile duct to the jejunal margin). The rate of absorption of micellar octanoic acid was about the same in normal and cirrhotic patients. There was no difference between cirrhotics with and without portacaval shunts in this respect. Patients with portacaval shunts had highest blood levels of octanoic acid (mean peak height 89.2 ± 19.6 mm). For those with cirrhosis mean peak height was 28.7 ± 2.7 mm and for controls it was 12.3 ± 2.4 mm.

- 10712 PORTAL HYPERTENSION AND DIGESTIVE HEMORRHAGE. (E.) De Almeida, A. D. (U. Sao Paulo, Brazil). Int. Surg. 46(1):57-60, 1966.

Portal pressures were measured by a column manometer in 69 patients with schistosomal cirrhosis or schistosomal hepatosplenic fibrosis via catheterization of the gastroepiploic vein in the gastric antrum immediately after opening the abdominal cavity. Thirty-six of the 69 patients presented gastrointestinal hemorrhage. The curves, portal pressure vs. hemorrhage and portal pressure vs. no hemorrhage, were almost identical. A statistical analysis of the hemorrhage data and portal pressure indicated that no relationship existed between the two. It is doubtful whether the best treatment to avoid hemorrhage in portal hypertension is to diminish the pressure of the portal system by portacaval shunts and similar procedures.

- 10713 CONTROLLED DIARRHEA IN THE TREATMENT OF CIRRHOSIS. (E.) Gertman, P. M. (Johns Hopkins U. Sch. Med., Baltimore, Md.), O. Gagnon and F. L. Iber. J.A.M.A. 197(4):257-260, 1966.

Patients with cirrhosis and ascites (11) and 3 control patients without liver disease were used in this study of water and salt loss via the intestinal tract after administration of mannitol in 10% soln. with twice the osmotic pressure of the plasma. Seven of the cirrhotic patients had been placed on a daily intake limited to 22 mEq of Na and 1500 ml of fluid, to reduce salt and water of edema, with only slight wt. loss. All urine and stools were collected and analyzed. After several days of observation patients and control subjects drank 2 liters of 10% mannitol each over a 4-hr. period. In several trials serial hematocrits were done on venous blood as a clue to the change in blood vol. during the course of the induced diarrhea. Nearly all patients had measurements of serum electrolyte levels and urea nitrogen immediately before and 24 hr. after ingestion of the hexose. During the study a broad series of blood tests were done frequently; a daily physical examination was given. Stools and urine were quantitatively analyzed for electrolytes, and also for mannitol; the total osmolarity of the stools was determined. In general, the sugar was well tolerated, the diarrhea (a non-gripping form) ending 3 hr. after intake of the soln. The av. values for the 11 patients and 3 controls for 24 hr. stool contents were, 14,130 ml of fluid, 123.8 g mannitol, and electrolytes expressed in mEq: Na, 155; K 75; Cl, 114; and bicarbonate, 77. The fluid was isosmotic with plasma. Some mannitol was absorbed and excreted in the urine. The Na excreted via the intestine always exceeded the K. The av. wt. loss in 24 hr. was 1.2 kg or 2.64 pounds.

- 10714 MEDICAL MANAGEMENT OF ASCITES IN HEPATIC CIRRHOSIS. (E.) Fu, F.-Y. (Inst. Schistosomiasis Res., Shanghai, China), M.-K. T'Ang, C.-S. Cheng, L. Hsien and S.-T. Lu. Chin. Med. J. (Peking) 85(5):302-307, 1966.

A survey of 107 cases (67 males, 40 females, age 15-60 yr.) of schistosomal cirrhosis of the liver complicated by ascites indicated that the general clinical status and liver function were the most significant prognostic factors; a basal 24-hr. urinary sodium below 2.0 mEq was associated with poor prognosis. In contrast, the duration of ascites, the magnitude of fluid accumulation, the number of courses of treatment or the type of diuretics used did not show such a determining effect. Of the 46 patients showing excellent responses, 15 were treated with supportive measures alone and 31 received supportive therapy and hydrochlorothiazide, alone or in combination with progesterone. Only 2 of the 24 patients whose ascites was controlled within 1-3 mo. responded to supportive therapy alone; the other 22 required additional diuretics. The 11 cases whose ascites subsided within 3-6 mo. all required diuretics. 9 patients also received aldactone. Of the 26 patients in the refractory group, 19 died of hepatic failure and 2 died of upper gastrointestinal hemorrhage; liver function in this group was extremely poor.

- 10715 SIGNIFICANCE OF EXCESS LYMPH IN THE THORACIC DUCT IN PATIENTS WITH HEPATIC CIRRHOSIS. (E.) Dumont, A. E. (New York U. Sch. Med., N. Y.) and M. H. V. Am. J. Surg. 112(3):401-406, 1966.

In patients with Laennec's cirrhosis, venting the distending thoracic duct by cannulation was followed by a decrease in liver size, disappearance of ascites, and reduction of portal vein pressure. After cannulation, massive hepatic enlargement decreased in 24-72 hr. to the extent that the edge of the liver was no longer

palpable. Apparently, the liver was distended because of an undrained vol. of interstitial fluid, since venting of the distended thoracic duct of dogs caused reversal towards normal of the lowered specific gravity of the liver. With drainage of the thoracic duct, ascites became much less prominent or disappeared entirely. In one patient the cannula was allowed to drain for 9 days, during which time there was a wt. loss of 40 pounds. Portal vein pressure fell within 2-18 hr. after establishment of rapid lymph flow from the thoracic duct. It is concluded that the thoracic duct, which is easily accessible through a simple surgical approach in the neck, is clearly an important source for the control of circulatory alterations associated with Laennec's cirrhosis.

Gallbladder and Biliary Tract Diseases

- 737 PRODUCTION OF BILE DUCT HYPERPLASIA AND GALLSTONES BY LITHOCHOLIC ACID. (E.) Palmer, R. H. (U. Chicago, Ill.) and Z. Hruban. J. Clin. Invest. 45(8):1255-1267, 1966.

ute and chronic effects of lithocholic acid (LA) and sodium lithocholate (SL) re investigated in rats by including these substances in the diet of the experimental animals. This diet, whether liquid or solid, was low in protein. The liquid et was force-fed and was used in the acute experiments having a duration of 6 and days. The liquid diet was also used for 1 mo. in one of the chronic experiments, th solid diet for 3 mo. following. Samples of tissue and some calculi removed om the livers were prepared for optical and electron microscopy. Gallstones were bjected to quantitative chemical analysis. In the chronic experiments large calculi re present in the common bile duct of all treated animals. The portal areas of ese treated livers showed marked bile duct proliferation and variable mononuclear ll invasion. The common bile duct was much hypertrophied. Hepatocytes were nerally intact with the normal amount of glycogen. Some ultrastructures (the lgi complex and the endoplasmic reticulum) had undergone hyperplasia. In still other series of rats the basic solid diet was fortified with sulfur containing ino acids in protein. The experimental rats on this fortified diet also received . The sulfur-containing amino acids inhibited gallstone formation in proportion the amount of bile acids conjugated with taurine.

- 738 DUODENAL DRAINAGE OF SULFOBROMOPHTHALEIN (BSP) IN HEPATOBILIARY DISEASE. (E.) Schoenfield, L. J. (Mayo Clinic, Rochester, Minn.). Gastroenterology 51(1):59-64, 1966.

ontrol tests of BSP duodenal drainage were done on 12 healthy volunteers and on 10 spital patients known to be free of biliary and liver diseases. Patients with own hepatobiliary disorders (68) were tested by the same method. After at least 4-hr. fast, the subject was intubated with a double lumen gastroduodenal tube. e gastric juice was discarded and the duodenal juice was collected. The adequacy the tube placement and the separation of the juices was considered satisfactory the duodenal juice had a pH of 7 or more, except when the gastric juice also had pH of 7 or more. Control blood was drawn from an antecubital vein and using the me needle, in situ, BSP (5 g/kg) was inj. rapidly and the time noted. The follow- g observations were recorded for each subject: (1) rate of flow of duodenal fluid; e time of the max. conc. of the dye in the fluid, and the percentage of BSP covered in the fluid 1 hr. after inj., (2) time of initial appearance of dye in e duodenal fluid, (3) percentage of dye in conjugated form in the juice during ch of the collection periods: (a) first 10 min., (b) next 40 min. and (c) last 10 n. The values recorded for all factors listed under 1 through 3 except the per- ntage of BSP conjugated in collection period b (or middle period) proved to be o variable for routine clinical use. The percentage of conjugated BSP proved to a sensitive indicator of primary hepatic parenchymal disease. Diminution (less an 50% in the middle period) occurred in all cases of hepatocellular disease. e mean normal value for the middle period was $64.4 \pm 8.7\%$.

- 739 EXTRAHEPATIC BILIARY ATRESIA: COMMENTS ON THE FREQUENCY OF POTENTIALLY OPERABLE CASES. (E.) Danks, D. M. (Royal Child. Hosp., Melbourne, Australia) and P. E. Campbell. J. Pediat. 69(1):21-29, 1966.

a 10-year period 35 infants with extrahepatic biliary atresia were encountered. enty-eight babies who presented obstructive jaundice and were investigated by erative liver biopsy and cholangiography are discussed. In 27, surgical dissec- on of the porta hepatis was performed. Laparotomy showed that when any lumen was und in the duct system, in all but 1 patient it was confined to the gallbladder to the gallbladder, cystic, or common ducts. Microscopic biopsy findings showed all but 1 patient portal tract fibrosis with associated bile duct fibrosis and aracteristically little change in pattern or arrangement of liver cells. Necropsy ndings on 14 of 24 children who have died showed that 6 had potentially operable sions. Five of these had been regarded as inoperable at laparotomy. One case onstrated that the ducts proximal to the atresia may fail to dilate until late

in the course of disease. In three cases the ducts may have dilated sufficiently to protrude at the porta hepatis only after surgical exploration. It is suggested that findings at laparotomy are not infallible and true frequency of potentially operable forms of biliary atresia is not known. Liver biopsy must be done in all presenting babies and necropsy of all who die in order to discover the true frequency.

- 10740 PERCUTANEOUS CHOLANGIOGRAPHY IN THE MANAGEMENT OF BILIARY STRICTURE. (E.) Walker, J. G. (Royal Free Hosp., London), W. B. Young, P. George and S. Sherlock. Gut 7(2):164-174, 1966.

Percutaneous transhepatic cholangiography using a flexible polyethylene catheter successfully outlined the biliary tree in 29 of 39 instances in patients with strictures of the bile duct whose biliary tree was unsatisfactorily outlined by oral or i.v. cholangiography. Previous operations for biliary reconstruction had been performed in 25 patients. In 13 instances the stricture was at the site of a previous anastomosis of a major bile duct to intestine and in 9 cases the common bile duct was involved and in 7 cases the stricture was particularly high, involving either the junction of right and left main hepatic ducts or the ducts themselves. In all but 1 case, operation was performed within 2 hr. and the cholangiographic findings were confirmed. No serious complication was encountered. In 9 instances where this procedure was unsuccessful, subsequent laparotomy revealed no significant biliary dilatation in 8, and evidence of sclerosing cholangitis in 3.

- 10741 ELECTROPHORETIC STUDIES OF LIPOPROTEINS OF GALLBLADDER BILE IN CHOLECYSTITIS. (Rus.) Sokolova, N. V. (Inst. Pediat. Med., Leningrad, USSR). Ter. Arkh. 38(5):60-63, 1966.

The content of lipoproteins (L) in the bile in 9 of 10 healthy persons was 0.1-0.17 optical units (oU); in 1 it was 0.32 oU. Of 55 patients with cholecystitis, in 27 with the chronic form treated by conservative measures the L content was lower, 0.02-0.09 oU (19 patients), or the same as in healthy subjects (8 patients); similar results were found in 6 chronic form patients treated by surgery; in 15 patients with exacerbation of the chronic form (8 with surgery) the L content was 0.02-0.1 oU; L were absent in 8 patients with phlegmonous cholecystitis; in 15 patients after cholecystectomy the L content in the bile (obtained after stimulation with magnesium sulfate) was low. The L content in 3 patients with cholangitis with exacerbation was up to 0.02 oU. In the absence of inflammation (12 patients) L content in bile equaled 0.01-0.08 oU. It was observed that at the minimum level of L in the bile (0.01-0.04 oU), the bile sediment showed a greater amount of crystals of cholesterol and calcium bilirubinate. The bile was obtained in 21 directly from gallbladder at cholecystectomy, and in 59 patients by duodenal sounding. It is possible that dysproteinemia has pathogenic significance in cholelithiasis and cholecystitis.

- 10742 BILE ACID COMPOSITION OF GALLSTONES FROM MAN. (E.) Schoenfield, L. J. (Karolinska Inst., Stockholm, Sweden), J. Sjövall and K. Sjövall. Dis. Colon Rectum 9(6):186-194, 1966.

The bile acids identified in human gallstones (15 samples: 10 mixed and 5 cholesterol type) by gas liquid chromatography were about the same as those in the gallbladder bile: deoxycholic, chenodeoxycholic and cholic acids were the principal components and lithocholic, ursodeoxycholic, 7-ketolithocholic and 12-ketolithocholic acids were present in small amounts. The centers of the gallstones contained a lower proportion of deoxycholic acid and less taurine-conjugated bile acids than did the remainder of the gallstones or the bile. These bile acid conc. in the center probably reflect the composition of bile at an earlier stage closer to the start of gallstone formation than that of the bathing bile in which the gallstones are found. This suggests that at the time of gallstone formation there may have been a disturbance in the enterohepatic circulation or in hepatic biliary excretion.

- 10743 AN EXPERIMENTAL STUDY OF BILIARY STRICTURES WITH EMPHASIS ON THEIR RELATIONSHIP TO THE COMMON CHANNEL. (E.) Orlay, G. (Prince Henry Hosp., U. New South Wales, Australia) and A. G. Liddel. Aust. New Zeal. J. Surg. 35(4):259-267, 1966.

method of assessing biliary strictures by means of an index of severity is presented along with the procedures performed on 33 dogs. Seven dogs, exposed to a variety of crushing injuries of the common bile duct, demonstrated no strictures except when injury was severe. Twenty dogs were exposed to a uniform injury of the common bile duct during construction of a pancreatico-choledochostomy. Thirteen of them survived more than 7 days and were studied. All exhibited strictures, 7 of which had severe ones. Inflammation of the bile ducts was detected, while for the most part only minimal pancreatic changes were found. All dogs experienced some degree of cholecystitis, the severity being proportional to the severity of stricture. Biliary amylase levels indicated patency of the pancreatico biliary anastomosis. Six dogs, exposed to uniform injury to the common bile duct along with choledcho-choledochostomy or lateral choledochotomy, showed no strictures and no cholecystitis. Indications are that trauma alone is not responsible for biliary strictures. It is possible that pancreatitis caused by the second procedure may have forced activated pancreatic juice to leak out and damage the bile duct. The development of choledochitis also may have increased the rate of stricture formation.

744 DIAMETER OF THE COMMON BILE DUCT IN CALCULOUS DISEASE OF THE GALLBLADDER AND BILE DUCTS. COMPARISON OF OPERATIVE AND ROENTGENOGRAPHIC MEASUREMENTS. (E.) Saypol, G. M. (New York U. Sch. Med., N. Y.), S. L. Beranbaum and R. O. Christman. St. Barnabas Hosp. Med. Bull. 1(5):53-57, 1966.

Uses of cholecystectomy for gallstones in acute and chronic cholecystitis (104), and of cholecystectomy and choledochostomy for gallstones and common duct stones (21) were studied. The diameter of the common bile duct was measured after cholecystectomy at a point just below the junction of the cystic duct with the former. If cholecystitis existed the fibrin was first stripped from the measurement area. Operative cholangiograms were performed and roentgenographic measurements made at the same locale. The technic for operative cholangiogram is presented. This technic, which utilized saline and hypaque, permitted the taking of only one X-ray of 120 of the 125 cases. In 15 patients with acute cholecystitis the av. diameter of the common bile duct was 10.8 mm. In 14 patients the diameter on operative cholangiogram was less by 1-7 mm. In 89 patients with chronic cholecystitis the av. diameter was 9.4 mm. In 88 patients the diameter on the operative cholangiogram was the same or less by 1-7 mm. In 21 patients the av. diameter was 15.6 mm. In all patients the operative cholangiogram was the same or less by 1-15 mm. In 14 of 15 patients with both operative and postoperative cholangiograms, X-ray measurements were the same or differed by 1-2 mm. X-ray measurements of the common bile duct are of the lumen and do not necessarily equal operative measurements which include duct walls. In ducts thickened by edema in acute cholecystitis, and by fibrosis with common duct stones, the operative measurement may exceed the X-ray measurement by 15 mm. In uncomplicated cholelithiasis measurements of ducts less than 10 mm on operative cholangiogram yield an accurate estimate of actual size of the common bile duct.

SUBJECT INDEX

Numbers followed by an asterisk (*) refer to abstracts in the text. Other numbers refer to citations only.

- ABDOMEN: 10004
 - acute: 10041
 - diagnosis: 9959
 - angina (see Mesentery, cardiovascular diseases)
 - ascites (see also Cirrhosis): 9660*,10611,10720
 - neoplasms: 10252
 - surgery: 10043
 - trauma: 9961
- ABSORPTION (see also Vitamins): 9628*,9629*,9638*,9639*,9643*
 - bile salts (see under Bile acids and salts)
 - bilirubin (see under Bilirubin)
 - carbohydrates: 9608*,9632*
 - glucose: 9619*,9627*,9635*
 - xylose: 10324*
 - drugs: 9634*,9641*
 - lipids: 9617*,9622*,9630*,9645*,10711*
 - fatty acid: 9644*,9646*
 - miscellaneous: 9642*,9649
 - protein: 9626*,9650,9651
 - amino acid: 9610*,9613*,9637*,9640*,9647
 - trace elements and minerals
 - calcium: 9618*
 - iron: 9609*,9611*,9614*,9615*,9633*,9648,9744*,10548
 - vitamins: 9625*,9636*
 - A and carotene: 9612*,9623*,9625*
 - B₁₂: 9621*,9669*
 - D: 9625*,10338
 - folic acid: 10334*
 - water and electrolytes: 9607*,9624*,9631*
- ACETYLCHOLINE (see Neurohumoral Agents)
- ACHALASIA: 10054*,10072,10095,10100,10117
- ADHESIONS: 10222*
- AFLATOXIN (see Liver, carcinogenesis; Stomach, carcinogenesis)
- AGING, effects of: 9846,10187,10334*,10384,10523*,10629
- ALBUMIN (see Liver, plasma proteins)
- ALCOHOL (see also Cirrhosis; Liver, fatty; Pancreatitis): 9752*,9777,10061,10272*,10724
- ALKALINE PHOSPHATASE (see Phosphatase)
- ALLERGY (see Immunology)
- AMEBIASIS: 9948,10001,10422
 - diagnosis: 9990
 - epidemiology: 10554
 - intestine: 10433
 - liver: 10591
 - treatment: 9926,10431
- AMMONIA (see Liver)
- AMYLASE (see also Pancreas): 9571,9700*,9701*,9702*
- ANEMIA (see also Cirrhosis; Malabsorption, treatment, vitamin B₁₂; Folic Acid; Malabsorption, iron; Liver, diseases): 9744*,10027,10128*,10137*,10142*,10143*,10161,10187,10214,10271,10607
- ANOREXIA NERVOSA: 10182
- ANTACIDS: 9641*
- ANTIBIOTICS (see also Malabsorption, treatment, antibiotics): 9553*,9578,9580,9670*,9814,9916,9933,9940,10008,10013,10020,10042,10090,10024,10339*,10349*,10355*,10429*,10512*
- ANTICHOLINERGIC AGENTS (see also under organs and diseases): 9848,10237
- ANTIEMETICS (see under Vomiting)
- ANUS
 - anomalies: 10392,10412,10435
 - diseases: 10402,10416
 - sphincters: 9584*,10359,10379,10417
 - surgery: 10396,10414,10415,10416
- AORTOGRAPHY (see Diagnostic Procedures)
- ASCITES (see Abdomen, ascites)
- BACTERIA (see Microorganisms)
- BEZOARS: 10129*,10150,10173
- BILE: 10076,10224*
 - composition: 9696,9750*,10741*,10742*
 - secretion: 9749*,9757*,9766*,9767*,9774*,9799,9803,9809,9814,10524*
- BILE ACIDS AND SALTS: 9628*,9785,9789,9792,10742*
 - absorption: 9620*
- BILE DUCT (see Biliary Tract)
- BILIARY TRACT (see also Gallbladder)
 - anomalies: 10739*
 - cancer: 10593,10748
 - cholangiography: 9598*,10261,10546,10740*,10744*,10745,10746,10747
 - common duct: 9598*,9697,9723*,10560,10743*,10744*,10756,10758,10761,10764
 - diagnosis: 10738*
 - diseases (see also under Cholecystitis; Cholelithiasis): 10737*,10751,10754,10760,10763
 - fistula: 10312
 - hemobilia: 10638*,10642*
 - morphology: 9591*,9598*
 - physiology: 9723*
 - Sphincter of Oddi: 10312,10762
 - stricture: 10560,10740*,10743*,10752
 - surgery: 9861,9923,10540,10723,10739*
- BILIRUBIN: 9583,9599*,9620*,9691*,9740*,9742*,9774*,9804,9812,9842,10502*,10578,10617
- BIOPSY (see under individual organs)
- BLEEDING (see also Ulcer, peptic): 9747*,9951,9952,9953,9994,10002,10018,10050,10185,10190,10424,10712*
 - diagnosis: 9917
 - treatment: 9901,9902
 - surgery: 9900
- BLOOD COAGULATION (see also Cirrhosis)
 - liver diseases: 10535,10553,10550,10696
- BLOOD GROUPS (see under Genetic Relationships)
- BRADYKININ: 10480*
- BUDD-CHIARI SYNDROME: 10574,10614
- CANCER (see also under individual organs): 9896,9972,9973,9974
 - diagnosis: 9975

IPATION: 9839,10353*
COSTEROIDS: 9585*,9738*,9752*,9754*,9784,
283,10321,10457,10687*
IS DISEASE (see Enteritis, regional)
C FIBROSIS (see Mucoviscidosis)
OSTIC PROCEDURES (see under Gastrointestinal
act, diagnosis; specific organs and diseases)
HEA: 9840,9844,10333*,10440,10713*
THERAPY (see Nutrition)
TION (see also Bile; Intestine, Small;
ncreas): 9559*,9573,9685*,9704*,9705*,
08*,9709,9711,9831,10429
rbohydrate: 9694,9700*,10332*
pid: 9623*,9807
otein: 9650
TICULA (see under specific organs)

DIVERTICULITIS (see under specific organs;
Malabsorption)
DUMPING SYNDROME (see Gastrectomy, complications,
dumping syndrome)
DUODENUM (see also Intestine, small): 9562*,
9654*,9656*,9714*,9853,9857,9964,9993,10233*,
10238,10247,10254,10271*
diseases (see also under Ulcer): 9723*,10237,
10241,10245,10256,10263
diverticula: 10260,10261
morphology: 9589*
DYSENTERY (see also Amebiasis; Shigellosis;
Typhoid Fever): 9948
diagnosis: 9826*
treatment: 9871*,10000*,10042*

EMBRYOLOGY (see Gastrointestinal Tract, develop-
ment)

EMESIS (see Vomiting)

ENTERITIS (see also Colitis; Enterocolitis;
Gastroenteritis): 9844,10013,10014,10230*,
10259

ENTERITIS, REGIONAL: 10321*,10322,10323

ENTEROCOLITIS (see also Colitis; Gastroenteritis):
9924,9968,10019,10020
staphylococcal: 10355*

ENZYMES, MISCELLANEOUS (see also Amylase; Liver,
enzymes, parenchymal; Pancreas, secretion;
Phosphatase; Stomach, secretion, pepsin): 9561*,
9565*,9568,9572,9575,9582,9639*,9692*,9693*,
9756*,9834,9877*,9896,10126*,10352*

ESOPHAGITIS: 10053*,10076,10077,10089,10114

ESOPHAGUS (see also under Achalasia; Hernia)

anomalies: 10065,10110

associated diseases: 10087

cancer: 10063,10066,10073,10074,10075,10086,
10092,10097,10098,10099,10105,10109,10112,
10116,10119

diagnosis

esophagoscopy: 9856,10061,10075,10112

radiology: 10068,10103,10112

diseases: 9931,10055*,10064,10071,10095,10102,
10103,10108,10113

fistula: 10091,10110,10119

foreign bodies: 10067

Mallory-Weiss Syndrome: 10061,10062

morphology: 9604

motility: 9713*,10101,10113

perforation: 10107

prosthesis: 9980,10066,10096,10109

stricture: 10069,10070,10090,10093,10094,10116

surgery: 9895,9900,10054*,10073,10074,10094,
10098,10105,10106,10119

ulcer: 10115

varices: 10052*,10056*,10111

FAT (see Absorption, lipid; Digestion; Liver,
metabolism; Malabsorption)

FECES: 9644*,9704*,9937,9945,10332*,10340*,
10381,10713*

FISTULA (see also under individual organs): 9910,
9976

GALLBLADDER (see also Biliary Tract; Cholecystitis;
Cholelithiasis)

GALLBLADDER (Contd.)

diagnosis
 cholecystography: 10750
diseases: 10018,10751
function: 9733*
morphology: 9588*
surgery: 10517*
GASTRECTOMY (see also Malabsorption; Ulcer, surgery; Stomach, cancer): 10183,10189
 complications: 9923,10155,10188,10208,10209,10219
 anemia: 9669*,10169
 dumping syndrome: 10125*,10132*,10139*
 malabsorption: 10130*
 treatment: 10305
 technic: 9980,10154,10156,10184,10198,10207,10210,10218

GASTRIN (see Stomach, gastrin)

GASTRITIS: 10137*,10160*,10185*,10205*,10213*
 associated diseases: 10135*,10146*
 atrophic: 10142*,10143*,10145*,10146*,10163
 diagnosis: 10144*,10163
 etiology: 10135*
 experimental: 10146*
 pathology: 10142*,10143*,10145*,10158,10221
 treatment: 10143*

GASTROINTESTINAL TRACT (see also specific organs; Cancer)

 associated diseases: 10024,10048,10051
 development: 9575,9584*,9642*,9690*
 diagnosis: 9841,9860,9982
 radiology: 9845,9853,9858,9943
 angiography: 9965
 lymphography: 9963
 disease: 9869*,9875*,9899,9912,9914,9967,9979,10037,10049,10245
 etiology: 9981,9985,9986
 function: 9570,9574
 morphology: 9595*
 toxic effects: 9730*,9849,9850,9863*,9984
 treatment: 9832
 drug: 9569,9833,9844,9847,9848,9855,9859
 enzyme: 9831
 hormone: 9911
 surgery: 9895,9966

GASTROSCOPY (see Stomach, diagnosis, endoscopy)

GENETIC RELATIONSHIPS: 10211,10326*,10357*,10487,10606

GLUCAGON: 9795,9796

GLYCOGEN STORAGE DISEASE: 10624,10626

GROWTH AND DEVELOPMENT (see Gastrointestinal Tract, development and under specific organs)

HEMOCHROMATOSIS: 9744*,10225*,10610

HEMORRHAGE (see Bleeding)

HEMORRHOIDS: 10418

HEMOSIDEROSIS: 10225*,10548

HEPATIC VEIN THROMBOSIS (see Budd-Chiari Disease)

HEPATITIS (see also Hepatic Coma and entries under Liver): 10522*,10579,10606

 acute: 10503*,10532*,10628,10692

 associated disease: 10586,10679*

 chronic: 10530*,10575,10586,10629,10679,

 10694,10701

 complications: 10701,10702

 diagnosis: 10501*,10516*,10681*,10696,10697

HEPATITIS (Contd.)

 epidemiology: 10680*,10683*,10684*,10690*,10695,10698,10699
 etiology: 10679*,10684*
 experimental studies: 10530*,10669,10677*,10682*,10686*,10687*,10688*,10693
 toxic (see Liver, toxic agents)
 treatment: 10531*,10629
 viral: 10501*,10529*,10677*,10678*,10679*,10685*,10686*,10687*,10688*,10689*,10691,10693,10695,10696,10697,10698,10699,10700,10702,10703,10705
 acute: 10680*,10681*,10682*,10683*,10684*,10690*
 chronic: 10681*
 prophylaxis: 10680*

HEPATOLENTICULAR DEGENERATION (WILSON'S DISEASE)

10528*,10585

HEPATOMEGALY (see Liver, diagnosis)

HERNIA

 diaphragmatic: 10078,10079,10080,10082,10088,10187

 hiatal: 10081,10083,10084,10085,10087,10104,10118,10121

HIRSCHSPRUNG'S DISEASE (see Megacolon, congenita)

HISTAMINE: 9556*,9585*,9624*,9652*,9657*,9661*,

9662*,9663*,9675*,9676*,9686*,9687*,9688*,9689*,

9726*,9783,9833,9982,10126*,10133*,10141*,10142*,

HYPOTHERMIA: 9600*,10136*,10203,10499,10510*

ILEOCECAL VALVE: 9592*,9830*

ILEUM (see also Intestine, Small): 9722*,9727*,9731*,10225*,10226*,10255,10266,10353*

ILEUS (see also Intestine, Large, obstruction; Intestine, Small, obstruction): 9718*,10249

IMMUNOLOGY (see also specific organ; Microorganisms): 9556*,9567,9739*,9773*,9871*,9929,9936,9944,9949,10135*,10137*,10277*,1062,10682*

INTESTINE, LARGE (see also Appendix; Colitis; Constipation; Diarrhea; Dysentery; Enterocolitis; Ileocecal valve; Ileus; Intussusception; Megacolon; Rectum; Volvulus): 10370
 anomalies: 10393
 associated diseases: 10349*,10356*,10411

 benign tumors: 10358*,10369,10383,10387,

 10389,10405,10419,10437

 cancer: 9913,10348*,10354*,10358*,10360,

Preface

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from virtually every medical journal published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

Acknowledgment

We wish to acknowledge gratefully the assistance of the National Library of Medicine in the preparation of this publication. The National Library of Medicine, through MEDLARS (Medical Literature Analysis and Retrieval System), is providing a recurring bibliography of gastroenterology-related citations which forms a part of the literature included in this publication as citations or abstracts.

Use of funds for printing this publication
approved by the Director of the Bureau of
the Budget on August 26, 1965

For sale by the Superintendent of Documents, U.S. Government Printing
Office, Washington, D.C. 20402. Subscription price per year in the
United States, Canada, and Mexico, \$8.50; foreign \$10.75; and \$1.00
for single copy. Payment is required in advance, and check or money
order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by Index Medicus. For journals not covered by Index Medicus, the abbreviations (with some modifications) found in World Medical Periodicals 3rd Edition, are used.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotrophic hormone	mM	millimolar
admin.	administered, administration	μ M	micromolar
ADP	adenosine diphosphate	max.	maximum, maximal
ATP	adenosine triphosphate	mc, μ c	milli-, microcurie(s)
approx.	approximately	mg	milligram(s)
av.	average(d)	min.	minute(s)
°C	degrees centigrade	ml	milliliter(s)
cm	centimeter(s)	mm	millimeter(s)
CNS	central nervous system	mo.	month(s)
conc.	concentrate(d), concentration(s)	MTD	maximum tolerated dose
cpm	counts per minute	p.o.	orally
DNA	deoxyribonucleic acid	ppm	parts per million
e.g.	for example	r	Roentgen
g	gram(s)	RBC	red blood cells (erythrocyte)
μ g	microgram(s)	resp.	respectively
hr.	hour(s)	Rev.	review (only in cite)
i.m.	intramuscular	RNA	ribonucleic acid
inj.	injected, injection(s)	s.c.	subcutaneous
i.p.	intraperitoneal	soln.	solution(s)
I.U.	international unit(s)	U	unit(s)
i.v.	intravenous	UV	ultraviolet
kg	kilogram(s)	vol.	volume
LD ₅₀	median lethal dose(s)	WBC	white blood cells (leukocyte)
m	meter(s)		or count
M	molar	wk.	week(s)
mEq	milliequivalent(s)	wt.	weight(s)
		yr.	year(s)

PRE-CLINICAL SCIENCES

GENERAL

- 0765 RESPONSE OF Cercopithecus aethiops TO CHOLERA VIBRIO LIPOPOLYSACCHARIDE AND PSYCHOLOGICAL STRESS. (E.) Felsenfeld, O. (Tulane U. Delta Primate Res. Ctr., Covington, La.), C. W. Hill and W. E. Greer. Trans. Roy. Soc. Trop. Med. Hyg. 60(4):514-518, 1966.
- ervets (Cercopithecus aethiops) which were subjected to a stress environment prior vaccination with Watanabe's lipopolysaccharide antigen prepared from an El Tor vibrio (0.5 mg s.c., followed 7 days later by 1 mg i.m.) took more time to develop elevated serum agglutinin titers or coproantibodies and to show a serum capability to neutralize the toxigenicity of the vibrios. The toxicity-neutralizing capacity of the sera did not reach satisfactory levels during the first 2 wk. in the controls and not until 3 wk. in monkeys exposed to stress; apparently, an effective immunity against cholera in primates takes about 2 wk. Coproantibodies reached their maximum on day 2 and attained a new height (which did not differ significantly in the 2 groups) after the second dose. The vibriocidal titer dropped in all the animals 7 days after the first antigen, indicating a possible negative phase of immunity. The hemolysis-inhibiting activities of the sera were the same in both groups. Animals under stress had elevated serum cortisol levels, but the food intake and weight did not differ from that of the control group.
- 0766 THE INFLUENCE OF ERYTHROPHAGOCYTOSIS ON THE INTERACTION OF MACROPHAGES AND Salmonella IN VITRO. (E.) Gill, F. A. (N. Y. Hosp.-Cornell Med. Ctr., N. Y.), D. Kave and E. W. Hook. J. Exp. Med. 124(2):173-183, 1966.
- phagocytosis and killing of Salmonella typhimurium by mouse peritoneal macrophages was inhibited when the bacteria and antibody-coated homologous erythrocytes or heterologous erythrocytes were simultaneously exposed in vitro to the macrophages. No inhibition occurred when uncoated or disrupted antibody-coated homologous erythrocytes were used. The antibody-coated erythrocytes were prepared by incubation of washed mouse erythrocytes with anti-mouse erythrocyte serum which was prepared by injecting rabbits with mice erythrocytes. Degradation of S. typhimurium was inhibited in mouse peritoneal macrophages which had previously ingested antibody-coated homologous erythrocytes. Anti-mouse-erythrocyte serum was found to have a cytotoxic action on mouse macrophages, whereas the viability of the macrophages was not altered by phagocytosis of antibody-coated homologous erythrocytes or uncoated heterologous erythrocytes. These findings support the concept that mice with hemolytic anemia are more susceptible to Salmonella infection than are normal mice by demonstrating that erythrophagocytosis in vitro inhibits phagocytic, bactericidal and degradative activities of macrophages.
- 0767 EFFECTS OF DRUGS RELATED TO SEROTONIN ON WATER INTAKE AND DEFECATION IN RATS. IMPLICATIONS FOR BEHAVIORAL STUDIES. (E.) Joyce, D. (Birkbeck Coll., London) and A. Summerfield. Arch. Int. Pharmacodyn. 161(2):489-494, 1966.
- In male hooded rats, an increase in water intake is seen following i.p. inj. with either 5-hydroxytryptophan (5-HTP) or 5-hydroxytryptamine creatine sulfate. When doses were given according to a Latin square design, a dose-response relation was not evident. When the same dose of 5-HTP was given on successive days to the same animals, water intake increased with the dose on the first day, but this relation altered after 4 repeated doses. The same was true for the increased defecation seen with the initial dose of 5-HTP. While the admin. of bromlysergic acid diethylamide had no effect of its own on water intake or defecation in rats, when given prior to 5-HTP it completely prevented the effect of 5-HTP and water intake. Lysergic acid diethylamide-25 admin. alone did not affect water intake but it did cause marked defecation. A subsequent inj. of 5-HTP caused no defecation but its effect on water intake continued. These data demonstrate the importance of investigating drug properties before they are used in behavioral studies, particularly with an instrumental conditioning situation where water would be the reinforcer or in the open field test.

GENERAL

- 10768 RUBIDIUM⁸⁶ CLEARANCE DURING NEUROGENIC REDISTRIBUTION OF INTESTINAL BLOOD FLOW. (E.) Dresel, P. (U. Göteborg, Sweden), B. Folkow and I. Wallentin. *Acta Physiol. Scand.* 67(2):173-184, 1966.

Arterio-venous extraction of rubidium⁸⁶ (Ru⁸⁶) was recorded in the cat intestine, using 2 different technics of admin., the Harvard pulsatile pump to deliver a constant mean blood flow to the intestine, or a method in which the intestine was perfused from the heart via its normal arterial connections and no pump was used. The capillary transport coefficient (PS), intestinal blood flow resistance, and (in some experiments) the capillary filtration coefficient (CFC) were determined. There was a good correlation between the 2 methods to determine capillary surface area open to blood flow, but the total range of variation for PS was less than that for CFC, because exclusion of some part of the capillary circulation by precapillary sphincters caused the filtration to cease much more completely than diffusion. Therefore, CFC appeared to reflect the changing capillary surface area more accurately than PS. During autoregulatory escape, the normal vascular response to stimulation of the vasoconstrictor fibers, PS was decreased during this time, but usually much less than CFC. These results apparently exclude involvement of true arterio-venous shunts to any significant degree during activation of the vasoconstrictor nerves. It is concluded that if redistribution of blood flow from the mucosa towards the submucosa during autoregulatory escape utilized special low-resistance channels, these must allow for exchange of solutes, implying a situation of "physiological shunting" rather than "true shunting."

- 10769 A COMPLEX GROWTH FACTOR IN DUODENAL TISSUE. (E.) Ackerman, C. J. (Virgin Polytechnic Inst., Blacksburg). *J. Nutr.* 89(3):347-354, 1966.

When a commercial preparation of dry duodenal tissue was hydrolyzed and fractionated 5 fractions were found which were capable of reinstating growth in rats whose growth had been arrested by a 10-wk. diet containing 1% sulfaguanidine. All of these 5 fractions were stable to acid hydrolysis and insoluble in 0.1 N HCl, but they differed from each other with respect to their solubility in benzene, acetone and methanol, as well as their stability to alkaline hydrolysis. When Fraction 1 was extracted with NH₄OH, no thyroxine was found in the NH₄OH extract; and neither thyroxine nor triiodothyronine could be detected in these fractions by paper chromatography. Fraction 2 could be extracted with NH₄OH, but otherwise did not behave as if it contained any thyroid hormones. Neither thyroxine nor triiodothyronine could be detected in Fraction 3, 4 and 5. Six mo. after these fractions were prepared, there was no activity loss except in Fraction 5 which was totally inactive. During the fractionation, the division of an active fraction yielded products whose total activity was greater than the original fraction which suggests possible structural changes in the duodenal growth factor without loss of activity. It is concluded that this growth factor in the duodenal tissue was not thyroxine or triiodothyronine.

- 10770 DISTRIBUTION OF SEROTONIN (5-HYDROXYTRYPTAMINE) IN THE HUMAN GASTROINTESTINAL TRACT. CELLULAR LOCALIZATION BY MEANS OF FALCK'S FLUORESCENCE METHOD. (E.) Tobe, T. (Japan Baptist Hosp., Kyoto), M. Fujiwara and C. Tanaka. *Am. J. Gastroent.* 46(1):34-37, 1966.

By means of Falck's fluorescence method serotonin was localized at the cellular level in specimens of human stomach, duodenum, jejunum, colon, appendix, liver and pancreas. These specimens were all taken from normal tissue during abdominal surgery and were immediately frozen. In all cases, atropine was admin. 1 hr. prior to surgery as a premedication and surgery was performed under fluothane intubation anesthesia or dibucaine spinal anesthesia. The duodenum was found to contain the most cells with serotonin and these were distributed in Lieberkuhn's crypts, but not in Brunner's glands. Many cells containing serotonin were also located in the Lieberkuhn's crypts of the jejunum, as well as in the deeper layer of villi. In the stomach, cells containing serotonin were noted only in the deep layer of the mucous membrane which was adjacent to the submucosa. Only a few serotonin-containing cells were found in the colon and the appendix had the lowest population, while none were detected in either the liver or pancreas. The fact that the appendix which is rich in argentaffin cells had few cells containing serotonin clearly demonstrated

GENERAL

that although serotonin-producing cells are argentaffin, not all argentaffin cells contain serotonin. The serotonin-containing cells adhered closely to the basement membrane and even bulged into its outer surface; serotonin was always located at the base of these cells.

- 0771 GROWTH DEPRESSION AND PANCREATIC AND INTESTINAL CHANGES IN RATS FORCE-FED AMINO ACID DIETS CONTAINING SOYBEAN TRYPSIN INHIBITOR. (E.) Khayambashi, H. (U. California, Berkeley) and R. L. Lyman. *J. Nutr.* 89(4):455-464, 1966.

Rats were tube-fed a diet containing purified amino acids and soybean trypsin inhibitor (SBTI) at a conc. approximating that found in 14% soybean protein. The caloric and nitrogen intakes were maintained equivalent to the control rats fed the diet without SBTI. Animals fed SBTI gained less wt. (28 g, compared to 42 g) after 14 days on the diet and had a higher intestinal nitrogen content (5.8 mg, compared to 3.5 mg) and protease activity (0.510, compared to 0.110 U/10 min.). The difference in nitrogen content was due to an increase in trichloroacetic acid (TCA)-insoluble protein. SBTI had no effect on growth of rats fed diets deficient in methionine, threonine, and valine. Supplementation of these amino acids to the SBTI diet increased the pancreatic wt. (154 to 195 mg) and protease activity (3.0 to 5.7 mEq tyrosine $\times 10^2$), although these parameters were greater in the pancreas of rats fed SBTI with and without supplementation. SBTI increased the levels of amino acids in the TCA-insoluble precipitate of rat small intestine to about 7-9 times the controls; cystine was increased 17-fold and histidine 25-fold the control values. Growth depression in the SBTI-fed rats was unrelated to food intake, toxicity or interference with availability of dietary amino acids and probably resulted from loss of essential amino acids (methionine, threonine, and valine) by exaggerated SBTI-induced discharge of endogenous proteins from the pancreas into the intestine.

- 0772 DIFFERENTIATION OF PAROTID AND PANCREATIC AMYLASE IN HUMAN SERUM. (E.) Berk, J. E. (U. California Coll. Med., Los Angeles), S. Hayashi, R. L. Searcy and N. C. Hightower, Jr. *Am. J. Dig. Dis.* 11(9):695-701, 1966.

Amylases obtained from human serum, saliva and extracts of human parotid glands and pancreata were purified by gel filtration. The purified amylases were then placed on columns of polyacrylamide gel and electrophoretic separation performed in the conventional manner. After the front line had migrated anodally about 5 cm the columns were segmented, each segment eluted and the enzyme activity of the eluates determined by the dinitrosalicylic method. The purified amylases from the parotid gland and pancreas migrated at different rates on polyacrylamide. To confirm this the 2 tissue amylases were combined and subjected to disc electrophoresis when again the migration rates differed, the parotid amylase traveling more rapidly toward the anode. This was also the case when human pancreatic fluid and human saliva were used as enzyme sources. The amylase fraction of human serum was purified and subjected to disc electrophoresis. Normal serum amylase showed a polymorphic pattern; the 2 major peaks coincided with those of pancreatic and salivary amylases. In a patient with pancreatitis, the peak due to pancreatic amylase was increased in disc electrophoretic measurements. The physicochemical properties of the 2 amylases were very similar. The electrophoretic differences may be the result of differences in electrical charge, molecular wt. or both. This technic may serve as a tool to distinguish these amylases.

- 0773 COMPARISON OF EFFECTS OF Fe^{++} , Fe^{+++} , AND FERRITIN ON INTESTINAL CIRCULATION. (E.) Chou, C.-C. (Northwestern U. Med. Ctr., Illinois) and E. C. Texter, Jr. *Am. J. Physiol.* 210(6):1447-1450, 1966.

The study was performed in 17 anesthetized heparinized dogs. A pump was interposed between the right femoral artery and the distal portion of the superior mesenteric artery. Blood flow was adjusted so perfusion pressure equalled systemic arterial pressure. Blood pressure was measured in the aorta and in mesenteric artery and vein and the portal vein. Segmental mesenteric vascular resistance was determined and the effects of Fe^{++} (ferrous sulfate), Fe^{+++} (ferric chloride), and ferritin recorded. Fe^{++} did not have any effect, whereas Fe^{+++} and ferritin significantly decreased total and small vessel resistances of this vascular bed. It is suggested

GENERAL

that Fe^{+++} and ferritin may play a role in the development of the hypotensive state in iron intoxication and the shock that accompanies hepatic ischemia. Hypotension during hepatic ischemia and iron intoxication may result from decreased vascular resistance and a decrease in cardiac output resulting from pooling subsequent to mesenteric dilation and passive dilation due to increased portal vein pressure. The ferric ion and ferritin may have similar effects on other peripheral vascular beds which contribute to hypotension. The mechanism of shock might in some respects be similar to that following admin. of endotoxin in dogs.

- 10774 CORRELATION BETWEEN THE MOTOR AND SECRETORY COMPONENTS OF A FOOD CONDITIONED RESPONSE IN ONTOGENESIS OF PUPPIES. (Rus.) Troshikin, V. A. (Bogomolets Inst. Physiol., Kiev, USSR). Zhur. Vyssh. Nerv. Deiat. Pavlov 16(4):734-736, 1966.
- 10775 OBTAINING HIGH PURITY Cl. oedematiens ANATOXINS. (Rus.) Shemanova, G. F. (Gamalei Inst. Epidem., Moscow), E. V. Vlasova and S. A. Shamraeva. Zhur. Mikrobiol. 43(7):52-54, 1966.
- 10776 THE DYNAMICS OF TISSUE RESPIRATION OF THE PANCREAS, SPLEEN, LIVER AND KIDNEYS AFTER LIGATION OF THE CRANIAL, CAUDAL PANCREATODUODENAL AND SPLENIC ARTERIES. (Rus.) Khananaev, L. I. (Ivano-Frankovsk Med. Inst., USSR) and G. F. Grishilo. Biull. Eksp. Biol. Med. 62(7):27-30, 1966.

CELLULAR STRUCTURE AND MORPHOLOGY

- 0777 SOME HISTOCHEMICAL CHARACTERISTICS OF THE GASTRIC MUCOSA IN MAN. (Rus.)
Listotchkin, B. G. (Leningrad Sanit. Hyg. Med. Inst., USSR). Arkh. Anat.
51(7):109-111, 1966.

Gastric mucous membrane epithelium from 22 patients with duodenal ulcers and 39 patients undergoing aspiration biopsy was examined. Tectorial epithelia of the fundus and pylorus had a large content of neutral mucopolysaccharides, a moderate nucleic acid content (RNA content in the basal epithelium was higher than in the apical portion) and a small protein content, while acid mucopolysaccharides were absent. Neck gland cells in the apical zone contained neutral and acid mucopolysaccharides and large amounts of RNA, DNA, and protein, while cells of the pyloric gland neck were rich in nucleic acids but had less acid mucopolysaccharides. Supplementary cells contained neutral and acid mucopolysaccharides; these were not present in the lining cells of the fundus, but these cells had a moderate nucleic acid and protein content. The main cells of the fundus were rich in protein and RNA, while acid mucopolysaccharides were absent. The cells of the pyloric glands contained large amounts of neutral mucopolysaccharides, moderate amounts of nucleic acids, slight amounts of protein, and no acid mucopolysaccharides.

- 0778 STRUCTURE OF MUSCLES OF EXTRAHEPATIC BILE DUCTS. (Rus.) Iupatov, S. I.
Khirurgiia (Moskva) 42(5):47-51, 1966.

Normal gallbladder (23) and extrahepatic bile duct (25) specimens from infants, children and adults were studied. In the extrahepatic bile ducts, the smooth muscles were distributed irregularly. They formed large bunches in the intramural region of the common bile duct and in the region of transition between the gallbladder neck and bile duct. In other areas of the extrahepatic bile ducts, the muscle bundles and fibers created a more or less marked network. Significant individual variations and changes due to age and other factors were noted.

- 0779 ARTERIES OF THE HEAD OF THE PANCREAS. ANATOMO-RADIOLOGICAL STUDY. (It.)
Moretti, S. (U. Bologna, Italy). Ann. Radiol. Diagn. (Bologna) 38(6):
569-594, 1966.

Twenty cadaver pancreas specimens inj. with a micropaque suspension into the arterial circulation were studied for anatomic anomalies. Gastroduodenal, superior mesenteric, and splenic artery branches normally supply the pancreas. Two arterial pancreatico-duodenal arches (one anterior, one posterior) may vary and exist in single, double, triple, or quadruple form; 1 case of triple posterior arch, 2 of double posterior arches, and 7 double anterior arches were described. These single or multiple pancreaticoduodenal arches have rich anastomoses even in areas of full channel. These may anastomose with other intrapancreatic branches, such as the dorsal pancreatic and the pancreatic branch of the splenic artery, which do not strictly pertain to the arterial circulation of the head and even with arteries involved in the peripancreatic circulation such as the aberrant hepatic artery or the supraduodenal artery of Wilkins. The pancreatic arterial circulation is in close contact with that of adjacent organs such as the duodenum, liver, stomach, spleen, and stomach, thereby insuring a supply of blood when other sources may be diminished. The richness of the pancreatic head vascularization makes it more difficult to visualize the whole tripod during aortography or selective arteriography and renders pancreatic surgery more difficult.

- 0780 A STUDY BY MEANS OF VASCULAR CASTS OF SMALL VESSELS RELATED TO THE
MAMMALIAN PORTAL VEIN. (E.) Del Rio Lozano, I. (U. West Indies,
Jamaica) and W. H. H. Andrews. J. Anat. 100(3):665-673, 1966.

The classification of portal vessels into conducting and distributing veins was not entirely substantiated when vessels of adult dogs, cats, rabbits, guinea pigs, and rats were studied by means of neoprene vascular casts. In some cases, the large portal veins sent minute vessels to supply the lobule without the interposition of smaller "distributing" veins. In small portal tracts inlet venules, internal roots and radicular roots occurred separately, but in large tracts they were often connected in a complex manner, suggesting that at least some internal

CELLULAR STRUCTURE AND MORPHOLOGY

roots may act as afferent vessels to the biliary tract. A translobular vein was seen in rabbits and guinea pigs, which originated in the biliary vessels and terminated in the hepatic vein and appeared to have a strong muscular sphincter located near the hepatic venous end, all of which suggests a venous shunt. In animals other than the rat, one or more vessels were seen which connected the portal vein to the veins of the gallbladder with inlet venules leaving the central part of the vessel. Its dimensions suggested that blood may enter either end of this vessel and leave in the central part. Anastomoses between portal branches of different portal tracts or between portal branches and hepatic venous tributaries were infrequent, but 2 forms of direct hepatic arterial-portal venous anastomosis were present.

- 10781 A FINE STRUCTURAL STUDY OF LIVER CULTURE. (E.) Watanabe, H. (Nagoya U. Sch. Med., Showaku, Nagoya, Japan). Exp. Cell Res. 42(3):685-699, 1966. Liver parenchymal cells of newborn rats were polygonal in shape and had large round nuclei with 1 or 2 nucleoli and many granular mitochondria distributed in the cytoplasm. When newborn rat livers were explanted on a surface of reconstituted rat tail collagen, after 1 or 2 wk. a membranous spread of outgrowing cells from the explant was seen on the collagen substrate. The surface of the outgrowth was covered with large cells in close apposition to one another, giving an appearance of a monolayered epithelium, having the appearance of parenchymal cells described previously. Lying under the sheet of these parenchymal cells were many small spindle-shaped cells. Nuclei of these cells were elliptical in section and nucleoli were not prominent. They resembled endothelial cells and were regarded as mesenchymal cells. Electron microscopic studies of the liver parenchymal cells of a newborn rat showed relatively large spherical mitochondria with a characteristic cristae-free central lumen; those cells which were situated on the surface of the explant showed a striking decrease in mitochondrial size and irregular shapes. Many filamentous mitochondria were found. These morphological changes might represent dedifferentiation of the cells.

- 10782 THE GASTRIC ARGENTAFFIN CELL POPULATION OF THE RAT. (E.) Gregg, R. V. (U. Southern California Sch. Dent., Los Angeles). J. Morph. 119(1): 81-87, 1966.

In the normal rat stomach, the argentaffin cells were fairly evenly distributed over the antral area, being more populous in the pyloric region. The number of cells per unit area did not appear related to animal size. In the antrum the cells are usually restricted to the basal third of the mucosa lining the pits and glands. The cells are typically shaped like an ice cream cone, the oval nucleus occupying the widest portion of the cell. A band of mucosa, less than 1 mm wide, caudal to and paralleling the dividing ridge between the forestomach and the glandular portion, was occupied by a substantial number of argentaffin cells which were nearly completely absent from the forestomach and corpus. The argentaffin cell population is found in less than 30% of the total stomach by wt., a factor which should be considered in serotonin assays.

- 10783 IMMUNOHISTOCHEMICAL STUDY OF THE PLASMACYTES OF THE NORMAL HUMAN INTESTINAL MUCOSA. (Fr.) Crabbé, P. A. (Saint-Pierre U., Louvain, Belgium) and J. F. Heremans. Rev. Franc. Etud. Clin. Biol. 11(5):484-492, 1966.

Biopsies of the duodenal or jejunal mucosa of 10 patients undergoing surgery for various gastric diseases were frozen and incubated with fluorescent antisera against each of the 3 human immunoglobulins (γ A, γ M, and γ G); γ A and M immunosera were prepared from injections of rabbits or guinea pigs with the corresponding protein or from patients with γ A myeloma, while γ G immunosera came from normal sera. Six immunofluorescent studies of each specimen showed 352,000 cells/mm³ containing the γ A immunoglobulin, 51,000 cells/mm³ with γ M and 15,000 cells/mm³ containing the γ G immunoglobulin/mm³. Planimetric studies were conducted to determine cellular density. Irregularity of distribution of the plasma cells of the intestinal lamina propria probably accounts for the high values of standard deviations. No statistically significant differences were found among the subjects with

CELLULAR STRUCTURE AND MORPHOLOGY

respect to population densities containing γ A and γ G immunoglobulins, but there were greater variations for cells containing γ M immunoglobulins.

- 0784 TWENTY-FOUR-HOUR MITOTIC RHYTHM IN THE GASTRIC MUCOSAL EPITHELIUM OF WHITE RATS. (Rus.) Kliukina, L. B. (Inst. Oncol., Acad. Med. Sci., Leningrad, USSR). Vop. Onkol. 12(6):64-67, 1966.

In adult albino rats, the mitotic index in the gastric mucosa reached max. values at 9 A.M. and 6 P.M. in the cardia (17.94 and 13.22, resp.) and pylorus (30.05 and 18.83, resp.). A minimum mitotic activity was observed at 3 A.M. and 3 P.M. in the cardia (2.6 and 7.83, resp.) and pylorus (9.89 and 18.17, resp.). The daily changes in the mitotic rate were less marked in the cardia than in the pylorus.

- 0785 STAINING OF PANETH CELLS WITH THIOFLAVINE T. (E.) Burns, J. (Radcliffe Infirmary, Oxford, England) and R. Whitehead. Nature (London) 211(5050):769-771, 1966.

The dependence of Paneth cell uptake of thioflavine T on an acid moiety in hematoxylin is discussed. Previous immersion of formalin-fixed jejunal mucosa in Krut-say's acid hematoxylin potentiated the thioflavine T fluorescence of Paneth cells and cytoplasm of the muciphage and quenched the autofluorescence of the background, argentaffin cells, and nuclei. Exclusion of the HCl from the acid hematoxylin, together with studies in which other components were omitted, indicated that hematoxylin and HCl are most effective when together. A thioflavine T-Krutsay hematoxylin staining procedure resulted in bright fluorescence of the Paneth cell granules, but little fluorescence of the muciphage cytoplasm.

- 0786 EFFECT OF RIBOFLAVIN OR IRON DEFICIENCY ON THE CELL RENEWAL RATE OF INTESTINAL MUCOSA. (E.) Miyaji, K. (Kyushu U. Sch. Med., Japan) and Y. Hara. J. Vitamin. (Kyoto) 12:89-97, 1966.

The rate of cell renewal in the intestinal mucosa was studied by P^{32} incorporation into DNA in rats with active riboflavin deficiency (produced by 3-4 wk. on a deficient diet), chronic riboflavin deficiency (maintained on deficient diet for 30 days with 2 μ g riboflavin inj. every other day), acute anemia (produced by venesection for 10 days), and chronic iron deficiency (venesection and 6-7 mo. on deficient diet with .03% α , α -dipyridyl). In normal rats, P^{32} was incorporated into the DNA of epithelial cells rapidly for 10 hr., then more slowly until the max. was reached at 48 hr., suggesting the complete replacement of epithelial cells in about 48 hr. In both acute and chronic riboflavin deficiencies the renewal rate did not decrease; in fact, chronic riboflavin deficiency significantly increased the rate. Acute anemia due to venesection increased the cell renewal rate, while chronic iron deficiency markedly decreased it.

- 0787 STIMULATION OF LIVER GROWTH BY DRUGS. I. MORPHOLOGICAL ANALYSIS. (E.) Kunz, W. (U. Marburg, Germany), G. Schaudé, W. Schmid and M. Siess. Excerpta Med. (Int. Congr. Ser.) (115):113-137, 1966.

Previous studies (most of them written by the authors) concerning the mechanism of liver enlargement are summarized and discussed. The anatomical and biochemical differences between liver enlargement produced by hypertrophy of the cells without cell multiplication, and liver hyperplasia with multiplication of the cells are discussed, with particular reference to the effects of halogenated hydrocarbons, barbiturates, and anesthetics such as Halothane and related compounds.

- 10788 STUDIES OF THE MUCOPOLYSACCHARIDES OF THE HUMAN DUODENAL MUCOUS MEMBRANE. (Rus.) Sinitsina, V. F. (Dept. Cytol. Histol., Order Lenin State U., Leningrad, USSR). Arkh. Anat. 51(7):111-114, 1966.

In the normal human duodenal mucosa, the goblet cell secretion contained a complex of sialomucins with both carboxyl-containing and sulfated acid and neutral mucopolysaccharides. The neutral and sulfated mucopolysaccharides were seen in the basal part of the cells; the central portions contained acid and neutral mucopolysaccharides with sialomucins; the apical portions of the cells contained acid mucopolysaccharides and sialomucins. Only neutral mucopolysaccharides were seen in the granules of the Paneth cells and in the Brunner's cells.

CELLULAR STRUCTURE AND MORPHOLOGY

- 10789 ISOLATION OF THE EPITHELIAL CELLS OF THE RAT SMALL INTESTINE. (E.)
Perris, A. D. (Atom. Energy Canada Ltd., Chalk River, Ontario). Canad. J. Biochem. 44(6):687-693, 1966.

A new method for obtaining isolated intestinal epithelial cells is presented. Suspensions of these cells respire actively taking up O_2 linearly for about 40 min. When actively transported sugars are present in the medium, O_2 uptake is increased. It is suggested that such preparations may be useful in the study of intestinal function at the cellular level. The whole small intestine was removed from anesthetized rats, flushed out with 0.9% NaCl, then everted, filled with 0.9% NaCl to produce a slight distention, and incubated for 12 min. at room temperature in 50 ml Krebs'-Ringer-phosphate-saline containing 0.25% bovine serum albumin and 0.15% hyaluronidase (approx. 300 USP U/mg). The incubation medium was pregassed with O_2 and the incubation carried out in an atmosphere of O_2 accompanied by gentle agitation. Cells were released into the medium. Subsequent operations were carried out in the cold. The cell suspension was centrifuged for 5 min. at 1500 revolutions/min. The supernatant was decanted and the pellet of cells was resuspended twice in phosphate saline containing 1% bovine serum albumin. A typical preparation yielded 1 ml of packed cells. Some tests were made on these cell preparations. O_2 uptake was measured by the standard Warburg technic. The presence of bovine serum had definite effects. Even 0.25% seemed to protect the cells; as the conc. of albumin was increased up to 1%, O_2 consumption also increased, but fell again as the protein conc. exceeded 1%. Histologic examination was made of intestinal tissues from which cells were removed; smear slides were made of the free cells and examined and found to be normal except for a number of free nuclei.

- 10790 THE TERMINAL DISTRIBUTION OF THE HEPATIC ARTERY WITH SPECIAL REFERENCE TO ARTERIO-PORTAL ANASTOMOSIS. (E.) Mitra, S. K. (Royal Free Hosp., London). J. Anat. 100(3):651-663, 1966.

Distribution of the hepatic artery was studied in 10 Wistar albino rats and in 3 human livers by simultaneous inj. of India ink into the hepatic artery and of a carmine-gelatin mass into the portal vein. Arterial branches terminated in 4 ways: 1) as vasa vasorum in the wall of the hepatic artery and its main branches; 2) in the wall of the bile ducts, forming a capillary plexus which is joined by small veins to the portal veins; 3) by directly joining the portal vein, forming arterio-venous anastomoses (this type of communication was usually composed of arterioles of 9-12 μ m diameter), and 4) by joining sinusoids at the periphery of the lobules. There was no evidence of intralobular arterioles. This is the first reported demonstration of arterioportal anastomosis by an inj. and histological technic. It is concluded that arterial pressure is transmitted to the portal veins through this communication, thereby contributing to the maintenance of normal portal pressure.

- 10791 THE DISTRIBUTION OF IMMUNOGLOBULIN-CONTAINING CELLS AMONG THE HUMAN GASTROINTESTINAL TRACT. (E.) Crabbé, P. A. (St. Pierre U. Clin., Louvain, Belgium) and J. F. Heremans. Gastroenterology 51(3):305-316, 1966.

Mucosal specimens (mostly histologically normal) from the human stomach, duodenum, jejunum, colon, and rectum were studied by immunofluorescence. Plasma cells with γ A-immunoglobulin largely predominated in the large intestine and rectum, as previously for the duodenum and jejunum. Most gastric mucosal samples had the same prevalence of cells containing γ A-immunoglobulin; there were only 2 specimens with large numbers of cells containing γ M-immunoglobulin. Cells containing γ D-immunoglobulin were encountered only occasionally. The significance of these findings is discussed in detail.

- 10792 ULTRASTRUCTURAL LOCALIZATION OF ACID MUCOSUBSTANCES IN THE MOUSE COLON WITH IRON-CONTAINING STAINS. (E.) Wetzell, M. G. (NIH, Bethesda, Md.), B. K. Wetzell and S. S. Spicer. J. Cell. Biol. 30(2):299-315, 1966.

Using the rectosigmoid region of mouse colon, selective ultrastructural staining of acid mucosubstances was obtained in fixed cryostat sections with both ferric chloride and colloidal iron soln. These stained sites were identified histochemically as containing sulfo- and sialomucins. This specific staining was pH-dependent; the optimal pH was approx. 2. Globules within colonic goblet cells and within

CELLULAR STRUCTURE AND MORPHOLOGY

deep-crypt mucous cells and small vesicles of the superficial nongoblet epithelial cells as well as the Golgi lamellae within each of these cell types were the principal intracellular sites specifically stained. This staining within the several lamellae of the Golgi apparatus suggests that the latter is involved with the elaboration and/or formation of mucosubstances. Extracellular material which stained specifically with this technic was found on the surface of the epithelial microvilli and on the luminal surface of capillary endothelium. In addition, similar material formed a reticular network surrounding stromal cells, collagen bundles and various colonic connective tissue elements. No counterpart to this intercellular network has been reported in specimens prepared in ultrastructural routine studies. The degree of specificity for this described iron-staining method had not been established, but organelles such as nuclei, rough-surfaced endoplasmic reticulum and mitochondria were not stained.

- 0793 MUCOSAL CELLULAR POPULATIONS AND DISTRIBUTIONS IN THE NORMAL CANINE STOMACH. (E.) Ritchie, W. P., Jr. (U. Minnesota Med. Sch., Minneapolis), A. Barzilai and J. P. Delaney. Anat. Rec. 155(1):111-116, 1966.
The cellular population and distribution in the corpus of the canine stomach (determined from biopsies of 30 dogs) was as follows in each "swath" of full thickness mucosa over a width of 0.223 mm: mucous neck cells, av. 41 with a range of 2-60; parietal cells, av. 95 with a range of 42-292 and chief cells, av. 205 with a range of 85-431. The av. glandular thickness was 557 μ . Using 4 other dogs, more mucous neck cells were noted in the glands of the juxta-antral and cardiac zones than in those of the corpus. Few parietal and chief cells were noted in the cardiac zone. The zone of relative acellularity in the cardia extended at least 1 cm distal to the cardioesophageal junction. In the corpus, parietal and chief cells were abundant and evenly distributed. The junction area between the corpus and the antrum had a high mucous cell density and, unlike man, this junction is abrupt. No disparity in cell populations or thickness was detected between the greater and lesser curvatures or anterior and posterior walls. When the total gastric mucosal cellular population of the stomach for the av. 15-kg dog was calculated, it was found that the acid-pepsin secreting area has a vol. of 35 cm³, and, therefore, contains 4.3×10^8 parietal cells, 7.2×10^8 chief cells and 1.4×10^8 mucous neck cells.

ABSORPTION

- 10801 RATE OF PASSAGE OF CALCIUM-45 AND YTTRIUM-91 ALONG THE INTESTINE, AND CALCIUM ABSORPTION IN THE LAYING FOWL. (E.) Hurwitz, S. (Nat. U. Inst. Agr., Rehovoth, Israel) and A. Bar. *J. Nutr.* 89(3):311-316, 1966.

White Leghorn hens were dosed p.o. with 160 μC of Ca^{45} and Y^{91} each as chlorides, and directly into the duodenum (through an incision) of 4 μC of Ca^{45} and 4 μC of Y^{91} with 1 mg of calcium as chlorides. The p.o. dosed birds were killed at 0.5, 1, 2, 4 and 7 hr. The others were bled and killed at 15, 30, 60, 120 and 240 min. The intestines were immediately removed, divided into segments and prepared for analysis by drying and ashing. The ash was dissolved in acid and counted in a scintillation counter. Passage time of Y^{91} was estimated graphically using a method similar to that of Marcus and Lengemann. Passage time in the crop and along the intestinal tract was similar for Ca^{45} and Y^{91} ; Ca^{45} moved more rapidly from the stomach. Passage rate was highest in the duodenum and decreased progressively along the tract. Intestine to blood Ca^{45} was rapid for 30 min. following duodenal admin. but slowed thereafter. It is concluded that the most effective site of calcium absorption in the hen is the jejunum.

- 10802 PHOSPHORYLATION OF THIAMINE IN THE INTESTINAL WALL DURING ABSORPTION IN VIVO. (E.) Rindi, G. (U. Ferrara, Italy), U. Ventura, L. De Giuseppe and G. Sciorelli. *Experientia* 22(7):473-474, 1966.

Equivalent amounts of thiamine hydrochloride and thiamine-propyl-disulfide (TPS) in 5 ml saline were given p.o. to rats. After 2 hr. the rats were killed, the intestines emptied, washed and homogenized. Thiamine phosphate content (difference between total thiamine and free thiamine) was determined by a modified thiochrome method. Special modifications of this method allowed determination of TPS. Phosphorylated thiamine content was increased in relation to dose of both compounds; greater amounts of TPS were absorbed at 1 and 10 mg dosages (up to 500% of control). The increase of the phosphorylated thiamine content in the tissues was essentially due to thiamine diphosphate; the increase during absorption of 1 mg of TPS was greater than during 1 mg of thiamine hydrochloride.

- 10803 THE EFFECT OF PHLORIZIN ON THE POTENTIAL DIFFERENCE AND SHORT CIRCUIT CURRENT OF THE LARGE INTESTINE. (E.) Levin, R. J. (U. Sheffield, England). *Life Sci.* 5(17):1591-1596, 1966.

Bullfrog everted intestinal sacs were filled with and incubated in either buffered chloride or buffered sulfate soln. The potential difference (PD) across the wall of the sac was measured by 2 agar salt bridges in contact with the mucosal and serosal soln. Short circuit current was measured in tissue mounted between 2 flux chambers as a flat sheet. The av. increase in PD after addition of phlorizin (1×10^{-3} M) was 6.2 mv over the control PD of 33.3 mv. Addition of phlorizin immediately increased PD and maintained this level as a steady state for at least 30 min. Washing out the glycoside with fresh soln. caused the PD to fall back to normal levels. In the tissue clamped between flux chambers addition of phlorizin (5×10^{-4} M) to the mucosal soln. increased PD by 6.4 mv and the short circuit current by 9.5 μA . Replacing the soln. returned both to control levels. Addition of phlorizin to serosal fluid was not as effective as that placed in the mucosal soln. shown by the further addition of phlorizin to the mucosal soln. Similar increases were seen with tissues incubated in chloride saline. Anoxic conditions, gassing with 95% N_2 , 5% CO_2 , depressed both PD and short circuit current and was reversible with oxygen. Iodoacetamide (2 mM) and ouabain (0.1 mM) depressed both variables when added to the serosal soln. Ouabain had little effect when added to the mucosal soln. Phlorizin was active at conc. of 5×10^{-4} M in bullfrog small intestine in inhibiting the PD caused by the addition of glucose and galactose to the mucosal soln. On the basis of this latter experiment it is concluded that the phlorizin used was biologically active. It has previously been shown that the PD and short circuit current can be accounted for by sodium transfer from mucosa to serosa. It is suggested that phlorizin may act by making the mucosal membrane more permeable to sodium.

- 0804 ABSORPTION OF STEROLS BY INTESTINAL SLICES IN VITRO. (E.) Feldman, E. B. and B. Borgström. Biochim. Biophys. Acta 125(1):148-156, 1966.
 taurodeoxycholate, triolein, 1,3-diolein, 1-monoolein, and oleic acid were used as emulsifying agents in a study of the uptake of isotopically labeled cholesterol, sitosterol, and cholesterol ethers by intestinal slices in vitro. Emulsions in Krebs-Ringer's soln. were formed by sonication. Everted hamster intestinal rings (100-200 mg wet wt.) were incubated in 1 ml of emulsion containing 10 μ M of glucose in an atmosphere of 100% O₂ at 37° C in a shaking water bath. After incubation the rinsed tissue was homogenized. The homogenate, a sample of the original emulsion, and the emulsion in which the tissue was incubated (together with the rinsing fluid) were extracted. The extracted lipids were separated by thin layer silicic acid chromatography and the separate radioactivities determined by a scintillation counter. The uptake of cholesterol was reversible and required bile salt. Sitosterol uptake was quantitatively similar. No inhibition of absorption of either sterol was demonstrated when mixtures were used in the incubation experiments. Absorption of intact cholesterol ethers was greater than that of the free sterol. Unlike studies of glyceride and fatty acid absorption in vitro, the results with sterols differed from absorption data derived from intact animals, and did not conform to the per cent distribution into a micellar phase observed in vivo. The results of these experiments indicate that the absorption of sterols in tissue slices has no direct relationship to absorption of sterols in intact animals.
- 0805 INTESTINAL IRON ABSORPTION STUDIES USING IRON-52 AND ANGER POSITRON CAMERA. (E.) Fawwaz, R. A. (U. California, Berkeley), H. S. Winchell, M. Pollycove, T. Sargent, H. Anger and J. H. Lawrence. J. Nucl. Med. 7(8):569-574, 1966.
 Forty μ c of Fe⁵², a cyclotron-produced positron-emitting isotope with a half-life of 8.2 hr., were admin. p.o. with 4 mg ferrous sulfate to 6 fasting normal subjects. Data collected on one subject are presented. Photoscans of the abdomen using the Anger Positron Camera were taken throughout the study. Preceding the oral dose and at the conclusion of the experiment, iron turnover studies were performed using 2 μ c of transferrin bound Fe⁵⁹ i.v.; when the total absorbed dose was to be measured using Fe⁵⁹ and the whole body counter, 20-30 μ c of Fe⁵⁵ were inj. i.v. for continuous plasma iron turnover studies. Blood samples were taken at half-hr. intervals. Separation of Fe⁵² counts was done by counting the fresh blood samples and then re-counting in 7 days after Fe⁵² had disappeared. The max. rate of Fe⁵² absorption occurred between 30-60 min. and decreased slowly up to 10 hr. Photoscans of the abdomen indicated that at this time of max. absorption the iron dose was in the upper small intestine and stomach. Passage of the dose could be traced, i.e., -1½ hr. to the distal jejunal area, at 2-2½ hr. in the ileum, at 2½ to 3 hr. the jejunal area was outlined. After 8-8½ hr. the colon was reached, absorption rate at this time was very low but still detectable, the jejunum was still well outlined. Relative localization was confirmed by barium X-ray studies. The max. rate of absorption occurred at the time iron was in the upper tract. Iron retention in the proximal intestine occurred and may account for the slow phase of iron absorption.
- 0806 BILE AND THE ABSORPTION OF STRONTIUM AND IRON. (E.) Webling, D. D'A. (U. Adelaide, Adelaide, Australia) and E. S. Holdsworth. Biochem. J. 100(3):661-663, 1966.
 Vitamin D₃ (200 U 16 hr. before the experiment) increased the absorption of strontium from the intestine in ileal loops of chick intestine in vivo using the method of study developed by Webling and Holdsworth. Chick bile salts, the chief chick bile salt Na taurochenodeoxycholate, and Na lauryl sulfate all increased the absorption of strontium from the ileal loops of the rachitic chick. Very little strontium was soluble in butanol-benzene; however the presence of bile salts and Na lauryl sulfate greatly increased solubility. Ligation of the bile ducts in rats (48 hr. before the experiment) resulted in a decrease in the absorption of iron admin. as a sparingly soluble phosphate. Bile was not found to be involved with the absorption of iron in its water-soluble form (ferrous sulfate). The data suggest that absorption improves in the absence of bile. It is concluded that the behavior of iron differs from that of calcium (or strontium), where bile increases the absorption of the soluble ionic form.

ABSORPTION

- 10807 EFFECT OF NEOMYCIN AND KANAMYCIN UPON INTESTINAL ABSORPTION. (E.)
Faloon, W. W. (State U. New York, Syracuse), I. C. Paes, D. Woolfolk,
H. Nankin, K. Wallace and E. N. Haro. Ann. N. Y. Acad. Sci. 132(2):879-
887, 1966.

In 4 obese patients with normal intestinal functioning receiving a formula diet containing 1000 calories and 75 g fat/day, 12 g daily of neomycin increased fecal fat from 10 to 32 g daily. When kanamycin, 12 g/day, was given fecal fat increased from 1 to 25 g daily. In all instances fat excretion during kanamycin was less than during neomycin admin. Fecal nitrogen was increased and there was an increase in excretion of sodium, potassium, and calcium. In three similar patients the dose of neomycin was delivered by tube into the middle or distal ileum while the diet was taken normally. Diarrhea occurred in all 3 patients, fecal fat excretion dropped markedly, decreasing to normal levels in 2 of the 3 patients with admin. to the ileum. In vitro it was found that neomycin, kanamycin and paromomycin all precipitated bile. Neomycin (10 mg/ml) decreased bile acid conc. by 50%. Sodium glycocholate was precipitated by both neomycin and kanamycin, sodium taurocholate only by neomycin. Intestinal secretions recovered from 2 subjects following corn oil meals yielded precipitates following neomycin orally. In 2 subjects it was attempted to reverse the effects of neomycin by the addition of bile salts; in 1 a slight decrease in the steatorrhea was found following admin. by tube of bile salts into the ileum. It is concluded that both antibiotics, though poorly absorbed, are able to induce intestinal malabsorption which may be related to their effects on bile salt metabolism.

- 10808 THE INTESTINAL ABSORPTION OF VITAMIN B₆ COMPOUNDS BY THE RAT AND HAMSTER. (E.) Serebro, H. A. (Johns Hopkins U., Baltimore, Md.), H. M. Solomon, J. H. Johnson and T. R. Hendrix. Bull. Hopkins Hosp. 119(3):166-171, 1966.

The passage of tritium-labeled pyridoxine (142 mc/mM) across the intestinal wall was studied 1) in vitro in 7 rats and 7 hamsters by the everted gut sac technic of Wilson and Weisman. Five sacs were made from each rat and 4 from each hamster intestine. To measure the passage of pyridoxamine and pyridoxal phosphate the method of Cousin and Brown was adopted. 2) In vivo absorption of pyridoxine was studied by the inj. of various conc. of pyridoxamine into cannulated loops of proximal jejunum in anesthetized rats. Distribution was studied by inj. H³-labeled pyridoxine into similar loops and counting radioactivity in the intestine, liver, bile and urine. In the hamster the ratio of pyridoxine inside the sac to the conc. outside was 0.88; rats in contrast had serosa/mucosa ratios of 0.2, except for the terminal ileum segment where it was 0.36. It is concluded that pyridoxine passes through the intestinal wall of the hamster more readily than that of the rat, but in neither species was there active transport. Tritium labeled pyridoxine was present in the intestinal wall of both rat and hamster. Binding to the wall did not occur in the rat; binding to the intestinal wall did occur in the hamster, i.e. the ratio of conc. of pyridoxine in water of intestinal wall to conc. of pyridoxine in the mucosal soln. av. 1.5. The absorption of pyridoxamine and pyridoxal phosphate was similar to pyridoxine. Ninety per cent of all compounds were recovered. When water movement was stimulated by the addition of glucose, pyridoxine transport across the intestinal wall was increased. In the studies with labeled pyridoxine absorption for jejunal loops, 81% of the total radioactivity was found in the liver. It is concluded that the absorption of vitamin B₆ compounds occurs by simple passive diffusion, even at low conc., and this absorption is proportional to water absorption. The vitamin appears to be absorbed into the portal vein and thence into the liver. The liver appears to be the site of initial storage of B₆.

- 10809 THE EFFECT OF POTASSIUM ON THE INTESTINAL TRANSPORT OF GLUCOSE. (E.)
Czáky, T. Z. (U. Kentucky Coll. Med., Lexington) and P. M. Ho. J. Gen. Physiol. 50(1):113-128, 1966.

Rat jejunal loops were cannulated and perfused in situ with various isosmotic soln. of glucose, galactose and 3-o-methylglucose and Na₂SO₄ or K₂SO₄; samples were taken from the perfusate and the sugar analyzed. Potassium conc. in the lumen enhanced absorption of glucose but not of galactose or of 3-o-methylglucose. Potassium

mulation was apparent at higher glucose conc. where primarily carrier-mediated diffusion was involved in translocation. At high glucose conc. potassium stimulated transport even if it was the only cation in the lumen. The potassium-stimulated intestine produced more glycogen with higher specific activity than the control intestine. Lactic acid production by the intestine was markedly enhanced if the intestinal lumen was perfused with a soln. containing glucose and high potassium conc. It is concluded that potassium does not affect permeability or the specific sugar transport system of the intestine, but enhances intracellular metabolic disappearance of glucose, thereby creating a larger luminal intracellular conc. gradient which, in turn, enhances the rate of carrier-facilitated entry.

10 NOTE ON THE INFLUENCE OF AGE ON SODIUM AND POTASSIUM-ABSORPTION FROM THE INTESTINE OF THE RAT. (E.) Korbuly, D. (Inst. Expt. Gerontology, Basel, Switzerland). *Gerontologia (Basel)* 12(2):99-105, 1966.

10 ml isotonic NaCl soln. or KCl soln. (19 mg NaCl, or 24.4 mg KCl labeled with ^{24}Na or ^{42}K having activity of 1 $\mu\text{Ci/ml}$) were inj. into 20 cm intestinal loops of anesthetized rats 5-20 mo. of age. After 10 min. the soln. was collected, evaporated and counted. The total NaCl or KCl remaining in the soln. was determined. No significant differences in absorption were found in rats of different ages. Total absorption av. 30.1%, Na^{24} exchange av. 65%, K absorption av. 23.7%, K exchange av. 52.9%. The larger exchange with the isotope was shown to be partly independent from the absorption process in the living animal by the comparison of living and dead intestines.

11 ABSORPTION OF GLYCINE AND L-ALANINE BY THE HUMAN JEJUNUM. (E.) Fleshler, B. (Western Reserve U. Sch. Med., Cleveland, Ohio), J. H. Butt and J. D. Wismar. *J. Clin. Invest.* 45(9):1433-1441, 1966.

Fifty-five jejunal perfusion-aspiration studies were performed in 3 adult males by means of a double lumen tube assembly which was positioned by fluoroscopy so that the perfusion opening was distal to the duodeno-jejunal junction. The recovery opening was 15 cm distal to the perfusion opening. Perfusion (12 ml/min.) was done after overnight fasting with a soln. containing 0.5 g/100 ml polyethylene glycol, glycine and/or L-alanine and adequate NaCl to equal 300 mOsm/kg. Collections were made by siphonage. The first 30-min. collections were discarded. Perfusion and collection were continued for 1-1.5 hr. Osmolality of the aspirates fell only slightly during the collection period and pH rose only minimally. α -Amino nitrogen content of the aspirates was accounted for by the perfused amino acids recovered. Amino acid absorption was not impaired by deletion of sodium from the perfusate or by the substitution of mannitol. Absorption of glycine and L-alanine increased as its conc. was raised but was not directly proportional to conc. and reached a limiting value. In two subjects, apparent Michaelis constants were 75 and 34 mM/liter for glycine and 34 and 38 mM/liter for L-alanine. Corresponding apparent max. velocities were 13 and 16 for glycine and 12 and 18 for L-alanine. At equimolar conc. (50-300 mM/liter) L-alanine absorption always exceeded that of glycine when they were perfused together. When varying conc. of glycine were perfused with a constant L-alanine conc., glycine absorption decreased, suggesting competitive inhibition. It is concluded that glycine and L-alanine are absorbed by active transport processes and that they share the rate-limiting step for which L-alanine has great affinity.

12 DISTRIBUTION OF IRON IN THE DUODENO-JEJUNAL MUCOSA IN NORMAL MAN AND IN THE COURSE OF VARIOUS PATHOLOGIC CONDITIONS. HISTOCHEMICAL STUDY. (Fr.) Debray, C. (Bichat Hosp., Paris), D. Cattani, C. Marche and J. P. Jori. *Nouv. Rev. Franc. Hemat.* 6(3):435-440, 1966.

Biopsy fragments (599) from 82 subjects with various pathologic conditions such as hyperchromic anemia, chronic diarrhea and intestinal siderosis and including 37 from normal patients were fixed in formalin and stained by Turnbull's method. Iron appeared in the columnar epithelial cells of the intestinal mucosa and in the membrane of the villous apices. In the former, iron was in the form of bluish-green granules in the apical regions of the cell. Iron was found in the apical cytoplasm of the membrane villousities. On the lateral villi the

ABSORPTION

iron-containing macrophages were frequently dispersed between the basal membrane at the base of the epithelial cells and the lumen capillaries. Iron was found in 37 of the 82 subjects, solely in the epithelium of 7, solely in the membrane of 8 and in both of these sections in 12 patients. All gastrectomy biopsies, those with atrophy of the duodenal-jejunal villi and those with Biermer's anemia lacked iron in any form. An abundance was found, especially in the macrophages, in 41 biopsies from 4 subjects with intestinally caused hyperchromic anemia. Six of the 8 hypsideremic cases displayed a lack of iron, while iron was located in 6 hypersideremic cases and none was found in 7 patients.

- 10813 THE INFLUENCE OF TEA CATECHINS ON ASCORBIC ACID ABSORPTION IN THE GASTROINTESTINAL TRACT OF ANIMALS. (Rus.) Fedurov, V. V. (Bogomolets Med. Inst., Kiev, USSR) and N. M. Pokrasen. Vop. Pitan. 25(2):29-34, 1966.

Admin. of ascorbic acid (20 mg) alone or in combination with tea catechin mixture (20 mg) by gastric intubation to guinea pigs (300-400 g wt.), maintained for 7 days on diets free of vitamin C and P (bioflavonoid), resulted 12 or 24 hr. later in an increase in the level of vitamin C in brain, liver, kidney, spleen and adrenal gland. The increase was statistically significant only after 24 hr.; at that time the vitamin C level was somewhat lower than after 12 hr. The blood in the mesenteric vein of normal guinea pigs treated with ascorbic acid (50 mg) alone or combined with tea catechins (50 mg; gastric intubation) contained 1 hr. later more than 50% of dehydroascorbic acid. The percentage of dehydroascorbic acid was 63.4 after treatment with ascorbic acid alone, 84.4 after treatment with ascorbic acid and tea catechins as compared to 52.6 normally. The percentage of dehydroascorbic acid in the vein of small intestine of normal rabbits (up to 2 kg wt.) which received, in addition to urethan (0.7 g/kg wt.), ascorbic acid (100 mg) alone or combined with tea catechins (100 mg; into the small intestine) 1 hr. later was 78.4 or 94.5, resp. while 74.1% was found normally. The total level of vitamin C in both experiments similar for animals treated with ascorbic acid alone or in combination with tea catechins. Therefore, ascorbic acid is absorbed mainly as dehydroascorbic acid. The catechins facilitated conversion of vitamin C into its dehydro-form.

- 10814 GLUCOSE METABOLISM IN THE MUCOSA OF THE SMALL INTESTINE. GLYCOLYSIS IN SUBCELLULAR PREPARATIONS FROM THE CAT AND RAT. (E.) Srivastava, L. M. (U. Birmingham, England) and G. Hubscher. Biochem. J. 100(2):458-466, 1966.

Intestinal mucosa was collected from rats and cats and subcellular fractions prepared from homogenates as described by Hubscher *et al.* with the modification that homogenization was done in 0.3 M-mannitol instead of 0.3 M-sucrose. Glycolytic activity was measured by determination of lactic acid formation in supernatant fractions under optimum conditions with glucose, fructose, glucose-6-phosphate, fructose-1,6-diphosphate or 3-phosphoglycerate as substrate. When the first 4 substrates were used 80-107% of the glycolytic activity was recovered. Hexokinase and phosphofructokinase appeared to be the rate limiting enzymes. With subcellular preparations from cat and rat small intestine lactic acid was formed from ribose 5-phosphate. The proximal half of the intestine produced a higher rate of glycolysis with glucose 6-phosphate than the distal half. Starved (24-48 hr.) rat mucosa had 25% the glycolytic activity of fed controls due to a decrease in hexokinases. Starvation did not decrease the activities of glucose 6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase.

- 10815 ABSORPTION OF THIOCARLID IN MAN. (Ger.) Gubler, H. U. (U. Lausanne, Switzerland), G. Favez, N. Bergier, J.-M. Maillard and T. Friedrich. Beitr. Klin. Erforsch. Tuberk. 133(2):126-139, 1966.

In 73 normal subjects and tuberculosis patients treated with Thiocarlid (4,4'-diisoamylhydroxylthiocarbanilide; DAT) in single doses (1.5-6.0 g) or for 5-5 days (2 x 1.5 or 2 x 3.0 g/day), the blood levels of DAT reached tuberculostatic levels in 90% of subjects regardless of the number of doses or the type of preparation given (tablets or capsules with coarse, fine or mixed-size granules). Inhibitory levels of DAT (as shown by tuberculostatic effects *in vitro*) were seen about 4 hr.

ter treatment and often extended beyond 24 hr. The 4-hr. and 24-hr. blood levels are higher at the higher dosage. It is concluded that the preferable dosage form for DAT is 6.0 g/day in a single dose. There were no signs of cumulative effect. Blood levels of DAT were the criteria for its absorption rate.

816 THE ACTION OF FOLIC ACID ANTAGONISTS (METHOTREXATE) ON REGENERATION OF THE INTESTINAL MUCOSA. (Ger.) Eder, M. (Path. Inst., U. Munich, Germany), H. Rostock and G. Vogel. Virchow. Arch. Path. Anat. 341(2):164-176, 1966. Chronic and acute experiments with methotrexate were performed in mice; regeneration of the intestinal mucosa was studied by H^3 -thymidine uptake. In the chronic series, mice received methotrexate (12 μ g/100 g/day by intubation) and were sacrificed 4, 8, 14, and 21 days. The acute series of 30 mice received a single dose of methotrexate (400 μ g/100 g i.m.) and sacrificed 4-144 hr. later. Histological and autoradiographic studies performed on the mucosa of the duodenum, jejunum, ileum and ascending and descending colon showed slow atrophy of the villi over 2-3 wk., especially in the duodenum, in the chronic experiment; the pattern of thymidine incorporation seemed to indicate that atrophy was related to a loss of cells in the regenerating zone. In the acute experiment, an immediate damage of the regenerating zone, manifested by a loss of part of the cell population, was seen; this in turn resulted in increased DNA synthesis in the remaining cells. Migration of differentiated cells to the villi was interrupted during this period. This block of the regenerative process did not last over 4 days; thereafter, the regenerative function was normal and even slightly increased. In the colon mucosa where cellular regeneration is normally slower, the methotrexate block appeared to be of a lesser intensity.

817 VITAMIN D AND TRANSFER OF PLASMA CALCIUM TO INTESTINAL LUMEN IN CHICKS AND RATS. (E.) Wasserman, R. H. (New York State Veterinary Coll., Cornell U., Ithaca, N. Y.), A. N. Taylor and F. A. Kallfelz. Am. J. Physiol. 211(2):419-423, 1966. The influence of vitamin D (750 I.U. in rats, 500 I.U. in chicks, p.o.) on the transfer of Ca^{47} from plasma to intestinal lumen was studied in vivo in rachitic chicks and rats. The amount of Ca^{47} deposited into an intraluminal soln. was measured 2.5 min. after i.v. inj. (1 μ c in rats, 0.1 μ c in chicks). Vitamin D significantly increased the plasma-to-lumen flux of calcium across chick ileum and rat duodenum by factors of 2.7 and 1.9, resp. Lumen-to-plasma flux in both species was also enhanced by vitamin D. The effect of influx was not due to a transmural electropotential difference from vitamin D admin. or to differences in plasma calcium conc. It is suggested that the major direct effect of vitamin D is not on a unidirectionally oriented transport system of calcium, but rather on an increased diffusional permeability, which may consist of a change in membrane structure and/or an effect on calcium carrier synthesis.

818 ACTINOMYCIN D EFFECT ON LAG IN VITAMIN D-MEDIATED CALCIUM ABSORPTION IN THE CHICK. (E.) Norman, A. W. (U. California, Riverside). Am. J. Physiol. 211(3):829-834, 1966. The time lag between vitamin D_3 admin. and enhancement of calcium (Ca) absorption across the intestinal mucosa of the intact rachitic chick was studied. At vitamin D doses of 20,000, 100 or 10 I.U. (either p.o. or i.p.), the lag in response was 5-8, 10-15 and 15-25 hr., resp. After admin. of H^3 -vitamin D_3 (500 I.U. i.p.), a high level of radioactivity was found within 1 hr.; this level was maintained for 1 hr. in all tissues examined except the adrenals. A proposed hypothesis for the delay in biological response to vitamin D was that vitamin D had to induce the synthesis of the appropriate enzyme systems or the alteration of membrane structure necessary for Ca absorption. This hypothesis was tested with actinomycin D. If actinomycin D (10 μ g i.p.) was given at any time up to 5 hr. after vitamin treatment (100 I.U.), no stimulation of Ca absorption occurred. In addition, actinomycin treatment for 36-48 hr. induced vitamin D deficiency in vitamin D-treated chicks, suggesting a turnover time of 24-36 hr. for the biochemical machinery associated with vitamin D-mediated calcium absorption.

ABSORPTION

- 10819 KINETICS OF DISTRIBUTION OF D₂O IN CANINE INTESTINAL TISSUES. (E.)
Weiner, D. E. (U. Minnesota, Minneapolis) and E. Grim. Am. J. Physiol. 211(3):600-606, 1966.

The uptake of deuterium oxide (D₂O) by the mesentery, muscle, mucosa, and submucosa of isolated lower small intestinal segments, during up to 40 min. of perfusion with arterial blood of constant D₂O conc. (2.0 moles %) was studied in dogs. Water exchange in the several intestinal tissues was slower than could have been assumed for such a highly perfused structure from previous studies on liver, intestine and brain. All 4 tissues appeared to have 3 water compartments with the turnover constant of the slowest being in each case only 1-2%/min. It is suggested that 1 of the 3 compartments is identical with the extracellular space, the other 2 being intracellular; the slower of the 2 latter compartments was tentatively identified with the nucleus and mitochondria.

- 10820 SORPTION OF POTASSIUM IN THE SMALL AND THE LARGE INTESTINE. (E.)
Phillips, S. F. (Mayo Clinic Found., Rochester, Minn.) and C. F. Code. Am. J. Physiol. 211(3):607-613, 1966.

Thiry-Vella fistulas of the upper jejunum, lower ileum and proximal colon were made in dogs; the effect of changes in luminal potassium conc. on the exsorption, insorption and net sorption of potassium was determined by placing 25-ml samples of isotonic Tyrode soln. of varying sodium and potassium conc. into the loops. Unidirectional fluxes were determined with Na²², K⁴², and deuterium oxide. The rate of potassium exsorption was independent of its conc. in the luminal fluid, but both insorption and net sorption were conc. dependent. When luminal potassium conc. was equal to or less than that of blood, potassium was always enterisorbed; absorption was always seen when luminal potassium conc. exceeded blood conc. Minute, negative, mucosal-blood potential differences at each site were independent of luminal fluid potassium content. It is suggested that potassium insorption at each site is passive, and that active secretion may occur in the colon.

- 10821 INVESTIGATIONS INTO THE ORIGIN OF CHANGES IN THE INTESTINAL MUCOSA FOLLOWING SUBLIMATE POISONING. (Ger.) Eder, M. (U. Munich, Germany) and K. Berthold. Naturwissenschaften 53(18):480-481, 1966.

Thymidine uptake and cell migration were studied in the duodenum, jejunum, ileum, and ascending and descending colon of mice treated with HgCl₂ (0.3 mg/100 g i.m.) 2-96 hr. previously. In all 24-hr. preparations, the labeled daughter cells had clearly migrated. The cells migrated to a distance of 25-33% of the height of a villus every 24 hr. between 24 and 72 hr. after treatment; after 96 hr. this migration increased, but was still below normal values. The number of cells rapidly synthesizing DNA increased in the ileum and descending colon 24 hr. after treatment; after 96 hr. this was seen in the jejunum, duodenum, and ascending colon. Total cell numbers also increased, parallel to the regenerative changes noted in the specimens.

- 10822 COMPARATIVE TESTS ON TISSUE UPTAKE OF IRON, COBALT AND COPPER IN ISOLATED JEJUNAL SEGMENTS OF THE RAT AND ON THE PASSAGE OF THESE IONS THROUGH THE INTESTINAL WALL. (Ger.) Forth, W. (U. Saarland, Homburg/Saar, Germany), W. Rummel, P. J. Becker and H. Andres. Med. Pharmacol. Exp. (Basel) 15(2):179-186, 1966.

Isolated jejunal segments from normal and anemic rats (av. hemoglobin values 14.6 and 5.6 g%, resp.) were suspended in physiological media containing 5×10^{-6} moles/1000 ml of FeSO₄, CoCl₂, or CuSO₄; corresponding radioactive anions (Fe⁵⁹, Co⁵⁸, and Cu⁶⁴, resp.) were added to the serosal side, and the disposition of radioactivity was studied 2 hr. later. In jejunal segments from anemic rats, the tissue uptake of iron and cobalt was increased by factors of 3.6 and 4.0, resp., and the passage of iron and cobalt ions from the mucosal to the serosal side of the jejunum was increased by factors of 10 and 3, resp., as compared to results seen in preparations from normal rats. There was no change in copper uptake or transport. It is concluded that in the presence of iron deficiency, the iron-binding system in the jejunal mucosa can distinguish between iron and copper, but not between iron and cobalt. The transfer system is more specific for iron, since the

SORPTION

crease of iron transfer in preparations from anemic rats was 3 times the increase cobalt transfer.

- 823 INFLUENCE OF CALCIUM SALTS ON THE ABSORPTION OF Ca AND Sr IN THE SMALL INTESTINE. (Ger.) Pany, J. E. (U. Vienna, Austria). Naturwissenschaften 53(18):480, 1966.

The influence of calcium salts on the diffusion and active transport of Ca and Sr in the small intestine was studied in 5-cm non-everted segments (closed at both ends) of duodenum and small intestine from rats, mice, and guinea pigs; the lumens contained the same soln. with the addition of Ca^{45} , Sr^{90} , and calcium gluconate or lactate in osmotically normal soln. Addition of calcium salts accelerated the passage of calcium through the intestinal epithelium. The external fluid showed higher calcium radioactivity than the controls, resulting in a higher Ca/Sr quotient, which was emphasized by the fact that the conc. of Sr^{90} was somewhat decreased. In the intestinal tissue, the Ca radioactivity was decreased as compared to the normal controls, and the Ca/Sr quotient was less than 1 as compared to 2-3 in trials without added Ca. These results were the same in the 3 species studied, being more pronounced in the guinea pig. A more intensive effect resulted from addition of Ca gluconate than from Ca lactate. The O_2 consumption and the respiratory quotient were normal for all trials. Cyanide- and N_2 -treated tissue preparations were used to determine the values of physical diffusion in this experimental method. The av. Ca/Sr quotients for the intestinal segments of rats were: 2.35 for simple diffusion; 2.54 for Krebs-Ringer soln. alone; 3.70 with added calcium gluconate; and 3.12 with added calcium lactate. These results raise the question of the existence of a carrier system, which under normal conditions is almost entirely inhibited.

- 824 FLUID TRANSPORT IN THE RABBIT GALLBLADDER. A COMBINED PHYSIOLOGICAL AND ELECTRON MICROSCOPIC STUDY. (E.) Kaye, G. I. (Columbia U., New York), H. O. Wheeler, R. T. Whitlock and N. Lane. J. Cell Biol. 30(2):237-268, 1966.

The fine structure of the rabbit gallbladder was studied in specimens of undetermined functional state (which were fixed either in situ or directly after removal from the animal); in specimens with absorptive function that had been experimentally terminated in vitro; and in specimens in which the rate of fluid absorption had been terminated in vivo or in vitro immediately before fixation. There was considerable variation in the width of the epithelial intercellular spaces in gallbladders of determined functional state. In gallbladders known to be transporting fluid, whether in vivo or in vitro, intercellular spaces and subepithelial capillaries were widely distended; distention was greatest in gallbladders that had been functioning in vitro. Elimination of either Na^+ or Cl^- from the media abolished fluid transport across the gallbladder wall in vitro. Epithelial intercellular spaces of biopsies taken from several gallbladders under these conditions were about 200 Å in width, except for minor distention at the crests of mucosal folds. Addition of the missing ion led quickly to re-establishment of fluid transport and distention of intercellular spaces throughout most of the epithelium. High conc. of Na were demonstrated in distended intercellular spaces; adenosine triphosphatase was localized along the lateral plasma membrane of the epithelial cells. An analogy is drawn between structure of the gallbladder mucosa and a serial membrane model proposed by Curran to account for coupled solute-solvent transport across epithelia. It is suggested that the intercellular compartment fulfills the conditions for the Curran model's middle compartment, and that active transport of solute across the lateral plasma membrane into the intercellular space may be responsible for fluid absorption by the gallbladder.

- 825 ABSORPTION OF PROTEIN AND FAT IN DOGS WITH INTERRUPTED MESENTERIC LYMPHATICS. (E.) Johnson, J. A. (U. Rochester, Rochester, N. Y.) and S. I. Schwartz. J. Oslo City Hosp. 16(8):173-183, 1966.

An increase in radioactivity was noted in the systemic blood of the anesthetized dog with intact mesenteric lymphatics when the mesenteric blood vessels were perfused

ABSORPTION

through a closed circuit (mesenteric vein to mesenteric artery) with approx. 250 ml of dog blood containing 100 μ c of ^{131} I-labeled serum albumin (RISA). All other drainage was completely interrupted by ligation and severance of the lymphatic structures. No increase in radioactivity occurred when the mesenteric lymphatics were interrupted. When RISA was infused into the jejunum the blood radioactivity rose rapidly reaching a peak at 90 min. and then fell; the highest levels were seen in animals with interrupted lymphatics. When ^{131} I triolein was infused, more radioactivity entered the system when the lymphatics were interrupted than when intact. In cross-perfusion experiments (femoral artery and vein of donor connected to the superior mesenteric artery and vein of the recipient with collateral circulation interrupted, lymphatics intact) infusion of RISA into the small intestine of the perfused animal resulted in no increase in radioactivity related to absorption of RISA; the perfusing animal showed a steep increase in radioactivity, demonstrating an absence of marked lymphatic transportation. These observations were considered to be in opposition to the usual view of the lymph as the main transport route for saturated long-chained fat radicals.

- 10826 HEXOSAMINE METABOLISM. II. EFFECT OF INSULIN AND PHLORIZIN ON THE ABSORPTION AND METABOLISM, IN VIVO, OF D-GLUCOSAMINE AND N-ACETYL-D-GLUCOSAMINE IN THE RAT: (E.) Capps, J. C. (U. Oklahoma Sch. Med., Oklahoma City), M. R. Shetlar and R. H. Bradford. Biochim. Biophys. Acta 127(1):205-212, 1966.

Fasted male rats treated with neomycin sulfate were used for the study. Groups were inj. s.c. with insulin (1.0 U/kg) 30 min. pretest or given five 0.25 ml s.c. inj. of 10% phlorhizin in oil at intervals of 12 hr. preceding admin. p.o. of soln. containing D-[1- C^{14}] glucosamine, D-[1- C^{14}] glucose, or N-acetyl-D-[1- C^{14}] glucosamine. Rats given glucose were sacrificed after 1 hr., all others after 3 hr. Insulin had no effect on the intestinal absorption coefficients of any of the sugars. The increase in percentage of absorbed radioactivity appearing as CO_2 in the animals was greatest following D-[1- C^{14}] glucosamine and least for N-acetyl-D-[1- C^{14}] glucosamine. Insulin produced no significant effects on the activity incorporated into serum, liver, and intestine. Insulin did increase absorbed radioactivity from either amino sugar into the hexose fractions of the liver and intestine which was taken to suggest that insulin alters the cellular transport or metabolism of glucosamine and N-acetyl-glucosamine. Phlorhizin strikingly decreased the intestinal absorption coefficient of N-acetyl-glucosamine and increased that of glucosamine. Although glucosuria was observed, this dose of phlorhizin did not affect the intestinal absorption of glucose. It is suggested that intestinal absorption of N-acetyl glucosamine probably involves passive transport. No explanation is apparent for the stimulation of glucosamine absorption produced by phlorhizin.

- 10827 THE MECHANISM OF CALCIUM TRANSPORT BY RAT INTESTINE. (E.) Helbock, H. J. (U. Southern California, Los Angeles), J. G. Forte and P. Saltman. Biochim. Biophys. Acta 126(1):81-93, 1966.

Calcium transport was studied in the rat intestine by 1) a modification of the Ussing short-circuit apparatus, 2) an organ bath for the study of everted intestinal segments, 3) in vivo by isolation of an intestinal segment by ligation. Ca^{45} was used as a tracer in the in vitro studies; for the whole animal studies Ca^{47} was used. Sodium transport was studied with Na^{22} . Activity was determined by liquid scintillation technics. In the absence of phosphate the movement of calcium was passive. There was no evidence for a membrane-bound carrier to facilitate its transport. Calcium flux was a linear function of its conc.; phosphate ions were actively transported from the mucosal to the serosal surface. In the presence of phosphate, calcium appeared to be actively transported, possibly as a counter-ion to the phosphate.

- 10828 STUDIES ON TRANSMURAL POTENTIALS IN VITRO IN RELATION TO INTESTINAL ABSORPTION. II. AN EFFECT OF OUABAIN ON GLUCOSE-DEPENDENT INCREMENT OF TRANSMURAL POTENTIAL OF RAT SMALL INTESTINE. (E.) Lyon, I. (Chicago Med. Sch., Ill.) and R. K. Crane. Biochim. Biophys. Acta 126(1):146-153, 1966.

influence of various sugars on the electrical potential difference (PD) measured across the wall of everted rat, hamster and guinea-pig intestinal sacs was studied. Confirming data previously published, the PD was increased in the presence of sugars known to accumulate against conc. difference. PD was strongly depressed by serosal ouabain (0.1 mM) and to a lesser extent with mucosal ouabain in the presence of added sugar. Increased PD in the presence of sugars was further increased by ouabain. This effect of ouabain was species specific, being evident in rats, to a lesser extent in guinea-pigs, and not at all in hamsters. In the rat no effect was observed in jejunal but not ileal sacs with D-glucose or 6-deoxy-D-glucose and with D-galactose in ileal but not jejunal sacs. Comparison of plots of PD against 1/glucose, or 6-deoxy-D-glucose, or galactose in the presence and absence of ouabain suggests that ouabain acts as a competitive activator for Na⁺ transport into the mucosal epithelial cell.

329 THE ORIGIN OF THE GLUCOSE DEPENDENT INCREASE IN POTENTIAL DIFFERENCE ACROSS THE TORTOISE SMALL INTESTINE. (E.) Wright, E. M. (U. Sheffield, England). *J. Physiol. (London)* 185(2):486-500, 1966.

Tortoise intestine mucosal preparations were studied by methods similar to those of Villien and Schoffeniels. Potential differences (PD) across the mucosal and serosal faces were determined with microelectrodes. Micropipettes (0.5 μ tip) were used to study PD across epithelial cells. Intracellular ion conc. were determined from tissue specimens. Glucose, galactose, α -methyl glucoside, 3-O-methyl copranose and sucrose all increased the transepithelial PD. Neither fructose or mannose produced an increase. The microelectrode studies demonstrated that PD changes due to glucose were accounted for by the increase in PD across the serosal face of the epithelial cells. Diffusion potentials were produced across the isolated mucosa by varying the ionic composition of either mucosal or serosal fluids. PD increases due to glucose were not decreased by reversal of ionic conc. gradients. It is concluded that the increased PD associated with the active transport of sugars across the small intestine is due to the presence of an electrogenic ion pump at the serosal face of the epithelial cell.

330 THE EFFECT OF ACUTE HAEMORRHAGE AND ACUTE HAEMOLYSIS ON THE INTESTINAL IRON ABSORPTION IN THE RAT. (E.) Chirasiri, L. (Hebrew U.-Hadassah Med. Sch., Jerusalem, Israel) and G. Izak. *Brit. J. Haemat.* 12(5):611-622, 1966.

Three groups of rats, normals, anemic due to daily bleedings (3-4 ml for 10 days), and anemic due to daily s.c. inj. of 1 ml of 2.5% phenylhydrazine soln./10 days were studied. The animals were fasted 18 hr. prior to the experiment. After they were anesthetized with ether the small intestine was divided into 5 segments separated by ligatures, mesenteric vessels remaining intact. Into each segment 10 μ Ci $^{59}\text{FeSO}_4$ was inj. mixed with 5 μ Ci $^{54}\text{FeSO}_4$. After 60 min. the segments were removed, ligatures removed, the abdominal wall closed. Rats were killed periodically and ^{59}Fe activity of blood and intestine determined, and the non-haem iron of various organs determined. Severe anemia was produced in both experimental groups, the bled group serum iron dropped, in the phenylhydrazine group it was elevated. Iron was distributed evenly throughout the intestinal wall; levels were increased following iron loading (inj. of 500 μ Ci $^{59}\text{FeSO}_4$ into a segment). Loading the first segment was slightly more effective in the normals and bled animals. The fifth segment was more effective for the third group. Absorption of radio-iron was most effective from the proximal segments. Radio-iron absorption was markedly increased in anemia rats, particularly in the distal segments; this increase was blocked by iron loading in the first or fifth segments. In controls 14% absorbed radio-iron was in the liver; first segment loading increased this, but fifth segment loading did not. Similar effects were seen in bled anemic rats. Hemolytic anemic rats did not change liver iron, iron loading in either the fifth or first segments increased liver iron. ^{56}Fe uptake by bone marrow in bled anemic rats was blocked by first segment loading; a similar effect in hemolytic anemic rats was produced by fifth segment loading. It is speculated that in these 2 types of anemia, different segments are stimulated to take up iron from the lumen. The body iron pool or the saturated plasma iron-binding protein conc. do not play a major role in the

ABSORPTION

regulation of iron absorption. The importance of intestinal iron conc. on the regulation of absorption is suggested by the data.

- 10831 THE EFFECT OF SODIUM ALGinate ON THE ABSORPTION OF STRONTIUM AND CALCIUM IN HUMAN SUBJECTS. (E.) Harrison, J. (U. Toronto, Toronto, Ontario, Canada), K. G. McNeill and A. Janiga. Canad. Med. Assn. J. 95(10): 532-534, 1966.

Sr⁸⁵ (2 μ c) and Ca⁴⁷ (2 μ c) were admin. p.o. with 100 mg of calcium chloride to 19 human subjects concurrently with a dose of sodium alginate given in a commercial jelly. Seven-day percent retentions of tracers were measured with a whole body counter. After 1 mo. the experiment was repeated without alginate. In 15 subjects 1.5 g of alginate reduced absorption of strontium by a factor of 2 with no significant effect on calcium absorption; 0.3 g alginate (2 subjects) appeared to have no effect on absorption of either tracer; 3.0 g of alginate (2 subjects) had no greater effect than the 1.5 g dose.

- 10832 EFFECT OF HYPOPHYSECTOMY, THYROIDECTOMY, ADRENALECTOMY AND ALLOXAN DIABETES ON INCORPORATION OF FATTY ACIDS INTO ESTERS BY THE SMALL INTESTINE *IN VITRO*. (E.) Gelb, A. M. (Mt. Sinai Hosp., New York). Metabolism 15(8):707-713, 1966.

Incorporation of a C¹⁴-labelled fatty acid (myristic acid, FA) by the small intestinal mucosa of rats and hamsters was studied *in vitro* by previously reported methods (Gelb *et al.*, 1964). Tissues from experimental and control animals were studied simultaneously. Tissues from hypophysectomized rats exhibited approx. twice the incorporation of FA as controls. Growth hormone (0.72 U/day/4-8 days s.c.) had no effects; cortisone (10 mg/day/8-12 days s.c.) significantly decreased incorporation of FA. L-Thyroxine (20 μ g/day/6-10 days s.c.) produced effects similar to those with cortisone. Replacement with body hormones was similar to each given singly. Dessicated thyroid (65 mg/day/13-17 days) decreased incorporation of FA in hypophysectomized rats. Thyroidectomy increased FA incorporation in rats; this effect was blocked to below control levels by L-thyroxine (50 μ g/day/12-16 days). Thyroid (65 mg/day/15-17 days) normalized incorporation. In hamsters similar doses of thyroxine normalized incorporation; thyroid (65 μ g/day) was less effective. Intestinal protein content and intestinal wt. were not found to be different in the various groups. Adrenalectomy was without effect on FA incorporation in rats and hamsters. Cortisone (5 mg/day/18-20 days) slightly increased FA incorporation in hamsters. Epinephrine and norepinephrine in the incubating soln. had no effect. Alloxan (35-40 mg/day/3-7 days s.c.) increased FA incorporation in hamsters. Glucose and insulin added to the incubation medium was without effect.

- 10833 BILE SALTS AND CALCIUM ABSORPTION. (E.) Webling, D. D'A. (U. Adelaide, Australia) and E. S. Holdsworth. Biochem. J. 100(3):652-660, 1966.

It was previously reported that bile enhances calcium absorption in the chick by aiding D₃ absorption, increasing solubility of calcium hydrogen phosphate and increasing absorption from water-soluble forms. Using the previously described methods both rachitic chicks and normal rats were studied. Calcium absorption was measured in chicks by the closed ileal loop method or by oral dosing; Ca⁴⁵ was used as a tracer in all studies. Bile and bile salts (chick bile, rabbit bile, taurocholate, glycocholate, taurochenodeoxycholate, glycochenodeoxycholate, scymnol sulfate and ranol sulfate) caused an increase in absorption of calcium hydrogen phosphate. In rats with ligated bile ducts the decreased calcium absorption was restored by admin. of bile salts. The bile salts increased solubility in water of the phytate and phosphate calcium salts at pH values between 6 and 8. Bile salts increased solubility of calcium in lipid solvents in approx. the same proportion as they increase the absorption of calcium from the gut. It is suggested that the actions of vitamin D and bile salts in calcium absorption could both be necessary for optimum calcium intake, particularly with poorly soluble forms of calcium.

- 10834 EFFECTS OF AN INCREASED DOSAGE OF CARRIER ON INTESTINAL ABSORPTION OF RADIOACTIVE CALCIUM (Ca⁴⁷Cl₂) AND RADIOACTIVE PHOSPHORUS (Na₂HP³²O₄) IN MAN. (It.) Gennari, C. (U. Siena, Italy), M. Bencini, V. Palazzuoli and L. Cesari. Boll. Soc. Ital. Biol. Sper. 42(10):589-592, 1966.

ORPTION

normal subjects received 40 μ c radioactive calcium chloride in 10 ml calcium carbonate, p.o. (= 88 mg calcium as carrier), followed in 1 wk. by the same p.o. dose in 50 ml water containing 2.94 g calcium lactic-gluconate (=500 mg ionized calcium as carrier). In 2 other subjects, the order of admin. was reversed. In 4 cases, increasing the amount of carrier as indicated resulted in significant reduction of serum radioactivity measured at intervals of 60-240 min. post-admin., though 2 of 3 subjects with normal rates of calcium absorption showed increased serum radioactivity in the presence of the larger dose of carrier at 15 min. after admin. and 1 of 3 continued to show this at 30 min. The fourth subject, with a reduced absorption rate for calcium, showed higher levels of serum radioactivity in presence of the smaller dose of carrier at all time intervals. A similar reduction of serum radioactivity was shown in 2 other normal subjects receiving triphosphorus, $\text{Na}_2\text{HP}^{32}\text{O}_4$, in 100 ml disodium orthophosphate, p.o. (= 800 mg phosphorus as carrier), as compared to 5 who received the same dose with only 80 phosphorus as carrier. It is concluded that increasing the dosage of carrier led to increase the actual amount which was absorbed from the intestinal lumen, thus reducing the actual amount of radioactive element reaching the circulating blood stream.

- 35 AMINO ACID TRANSPORT IN THE GOLDFISH INTESTINE. (E.) Mephram, T. B. (A.R.C. Inst. Anim. Physiol., Babraham, Cambridge, England) and M. W. Smith. J. Physiol. (London) 184(3):673-684, 1966.

Rectal sacs of goldfish anterior intestine or rectum were everted and made into open-ended sacs; the sacs were filled and bathed with bicarbonate saline containing the amino acid under test in conc. of 10 mM. During incubation transmural potentials were recorded. Threonine, alanine, serine, histidine, valine, methionine, phenylalanine and leucine were actively transported and the serosal transfer correlated with the steady potential and with the amino acid-evoked potential measured on the everted preparations. Rectum tissue actively transported alanine and the steady potential was raised when alanine bathed the mucosa of the everted preparation, L-threonine was partly transaminated to alanine by the intestine, rectum sacs transaminated alanine to an unidentified amino acid, possibly serine, asparagine or glutamine. It is suggested that L-amino acids increase the ease by which sodium enters the mucosal cell but that it is the rate at which this sodium is transported across the basal membrane which determines the net serosal transfer of amino acids.

- 36 THE PERMEABILITY OF THE GASTRIC MUCOSA OF DOG. (E.) Altamirano, M. (U. Chile Sch. Sci., Santiago) and C. Martinoya. J. Physiol. (London) 184(4):771-790, 1966.

A piece of the greater curvature of the dog stomach was mounted in a special organ chamber. The piece of mucosa remained connected to the dog by branches of the gastric artery and splenic vein. Venous blood samples were obtained by a catheter in a "tributary" vein. Test soln. were normally 0.295 M dextrose or 0.310 M urea free of salts. Labelled molecules, C^{14} -urea, C^{14} -thiourea, C^{14} -sucrose and C^{14} -hemoglobin (rat) were added to the soln. for permeability studies. Dextrose or urea were used to change the osmotic pressure. The mucosa behaved as a semi-permeable membrane, about 45×10^{-6} ml of water flowed/cm²/min. Permeability constants decreased with increased molecular vol. Non-electrolyte transport decreased when the chamber contained isosmotic dextrose, which was felt to be due to reduction of diffusion area by the high molecular vol. of dextrose. Decreases in transport by addition of solutes was considered evidence that the molecules diffuse through pores filled with water. Renkin's equation fitted the data collected if the assumption that the equivalent membrane has pores of at least 2 different radii was made. The results obtained would be handled adequately theoretically by the equivalent membrane pierced by parallel pores of at least two different diameters. A procedure was suggested for calculating the proportion of pores of different radii.

- 37 ROLES OF CITRIC ACID AND ASCORBIC ACIDS IN ENTERIC IRON ABSORPTION IN RATS. (E.) Hopping, J. M. (Kansas State U., Manhattan) and W. S. Ruliffson. Am. J. Physiol. 210(6):1316-1320, 1966.

ABSORPTION

Rat everted intestinal sacs (15 cm) were prepared. Only one sac was made from each rat, the intestine starting 1.5 cm from the pylorus being used. $\text{Fe}^{59}\text{Cl}_3$ was used as a tracer. Iron, citric acid and ascorbic acid transport were all found to be directly related to the conc. of citric or ascorbic acid in mucosal fluid. In each case the compounds were added only to the mucosal soln. There appeared to be a limited capacity for ferric citrate transport, suggesting transport by means other than passive diffusion. In vivo data, in situ loop method, using similar soln. as the in vitro studies but with substitution of FeSO_4 for FeCl_3 were collected. Radioactivity was determined for selected tissues and fluids. The reducing action of ascorbic acid in the lumen was found to be important; the vitamin was also thought to be a chelating agent or to have an independent reductive action at the serosal surface.

- 10838 EFFECT OF HISTAMINE ON ELECTROLYTE CHANGES IN SOLUTIONS INSTILLED IN RAT STOMACHS. (E.) Lindner, A. E. (New York U. Sch. Med., N. Y.). Am. J. Physiol. 210(6):1321-1326, 1966.

Isotonic glucose, saline, and acid saline soln. were instilled into stomach "pouches" in postvagotomy pylorus-ligated rats. The fore-stomach was excluded by ligation around the catheter used for the instillations. Two 45-min. test periods with 3 ml of soln. in the stomach were carried out, the soln. were recovered and analyzed. Calculated net fluxes showed similar secretion of sodium, chloride and potassium for all soln. No entry of hydrogen occurred with glucose and saline; hydrogen was lost with acid-saline. Glucose soln. became hypertonic, saline remained isotonic, acid-saline became hypotonic. Histamine (5 mg/100 g s.c. with isotonic soln.) increased secretion of HCl and potassium but not sodium output. Histamine had no significant effect on the electrolytes of the spontaneously secreting pylorus-ligated stomach. It is suggested that changes in potassium conc. after histamine may be related to processes of gastric stimulation rather than to HCl formation.

- 10839 THE STUDY OF ABSORPTION IN THE SMALL INTESTINE IN CHRONIC ENTEROCOLITIS WITH THE AID OF TAGGED ^{131}I LIPIDS. (Rus.) Prostiakov, K. M. (Inst. Med. Radiol., Obninsk, USSR), A. I. Ishmukhametov, R. I. Chanysheva, A. P. Kondratieva and R. S. Volzhanin. Ter. Arkh. 38(5):83-86, 1966.

- 10840 THE SIGNIFICANCE OF GASTRIC ANTIBODIES. (E.) (Rev.) Chanarin, I. (St. Mary's Hosp. Med. Sch., London) and S. Ardeman. Proc. Roy Soc. Med. 59(8):690-691, 1966.

- 10841 METOCLOPRAMIDE AND INTESTINAL ABSORPTION OF ISONIAZID. (It.) Savio, E. and P. Pontiggia. Ann. Med. Sondalo 13(6):402-405, 1966.

- 42 OSMOLALITY OF NORMAL HUMAN SALIVA AT BODY TEMPERATURE. (E.) Sawinski, V. J. (VA Hosp., Hines, Ill.), A. F. Goldberg and R. J. Loisel. Clin. Chem. 12(8):513-514, 1966.

Saliva samples were collected without stimulation 5 min. after a mouth rinse. Forty-two of the samples were analyzed for osmolality within 1 wk. Ninety other samples were analyzed after being frozen 1 yr. A Mechrolab vapor pressure osmometer was used for all determinations. This instrument allows measurement at any temperature, in this case body temperature. The av. osmolality for the fresh saliva was 49 mOsm/liter with a range of 16-88 mOsm/liter. The av. osmolality of the frozen samples was 38 mOsm/liter with a range of 10-91 mOsm/liter. The two groups were found to be significantly different. The differences were believed to be artifacts caused by changes in the proteins during storage, with possible chelation of the proteins with other solutes.

- 43 MICROPUNCTURE STUDY OF SUBMAXILLARY GLANDS OF ADULT RATS. (E.) Martinez, J. R. (Free U., Berlin, Germany), H. Holzgreve and A. Frick. Pflueger. Arch. Ges. Physiol. 290(2):124-133, 1966.

Submaxillary glands in 28 fasted male rats exposed through a midline neck incision were studied by micropuncture technics. Glass capillary micropipettes were used to collect samples. At the level of the intercalated ducts pipettes of 100 μ tips were used; tips up to 15 μ were used at other levels; samples were also obtained at the duct orifice in the mouth. Samples ranged from 1 to 10 μ l. Micropipettes were filled with colored oil which was inj. into the duct to delineate before the oil and the sample were aspirated. Freezing point depression and Na and Cl conc. were measured by the methods of Ramsay et al. Na conc. was determined by flame photometry. Potassium conc. was measured with an Eppendorf flame photometer. The av. osmolality of samples from the intercalated ducts was 307 mOsm/liter, av. Na conc. 146 mEq/liter, av. chloride conc. 121 mEq/liter. In samples from the main excretory duct av. osmolality was 229 mOsm/liter, Na 117 mEq, chloride 108 mEq/liter. Final saliva (duct opening) av. osmolality was 89 mOsm/liter, Na of 21 mEq/liter and chloride 55 mEq/liter. The corresponding 3 values for serum were: 311 mOsm/liter, 146 mEq/liter and 120 mEq/liter. The conc. in ducts were not significantly different from those in samples from the intercalated ducts. The decrease in osmotic pressure and sodium and chloride conc. takes place mainly in the main duct. From these findings it is concluded that saliva becomes hypotonic by the active reabsorption of sodium chloride out of the isotonic primary secretion by a mechanism located in the main excretory duct.

- 44 POTASSIUM, SODIUM AND CHLORIDES IN GASTRIN-STIMULATED GASTRIC SECRETION IN MAN. (E.) Semb, L. S. (Ullevål Hosp., Oslo, Norway). Scand. J. Clin. Lab. Invest. 18(4):417-424, 1966.

Gastric juice was collected at 20-min. intervals by Levin tube in 10 patients for 1 hr. before and after admin. of gastrin (2 μ g/kg). Total acid was determined by titration. K and Na were determined by flame photometry; chlorides were determined by chloride meter. Serum electrolytes were determined under fasting conditions and after gastrin. Serum electrolytes were unchanged after gastrin admin. Gastrin was admin. at least twice to each patient studied. Total acid and Cl, total acid and K were significantly correlated. A negative correlation existed between total acid and Na. There was no correlation between K and Na or between K output and Na output. K output and Cl output were significantly correlated after gastrin. The electrolyte levels measured were highly reproducible, both before and after gastrin. Sodium was the most stable parameter. The patterns of electrolyte and acid secretion were found to be very similar to those following histamine admin.

- 5 EFFECT OF GASTRIC SECRETIONS ON THE SPHINCTER OF ODDI. (It.) De Rosa, R. (City Hosp., Karlsruhe, Germany) and M. Hatano. Minerva Med. 57(31):1412-1415, 1966.

In cholecystectomized patients in whom calculi could not be demonstrated, previously aspirated gastric secretion was reintroduced by gastric sound in such a manner as to flood the area surrounding the papilla of Vater. Intracholedochal

SECRETION

manometric pressure was unchanged in 4 of 10; in 6 of 10, an increase of 1-2 cm was attributed to spilling of the liquid into the duodenum. In mature Indochinese pigs, which have separate papillae for the introduction of bile and pancreatic secretion into the duodenum, oddoelectrographic, photographic and direct observations were made of the sphincter of Oddi's response to hydrochloric acid lavage of the mucosa of the papillary area after the animals were subjected to a longitudinal duodenotomy. Increasing pH of the hydrochloric acid soln. resulted in progressive acceleration of the rhythm of sphincteral contraction, accompanied by increase of the diameter of the opening. With progressive increase of pH value above 3.0, further acceleration of the contractual rhythm was accompanied by progressive decrease of the amplitude of contractions, resulting from the degree of dilatation of the opening and culminating in semiparalysis of the sphincter with its aperture opened to the max. diameter possible. It is concluded that a compensatory regulatory mechanism exists, whose function is to balance gastric secretion against bile flow in such fashion as to maintain duodenal chyme on the alkaline side.

- 10846 FOLIC ACID ACTIVITIES OF SALIVA, SERUM AND URINE. (E.) Mäkilä, E. (U. Turku, Finland). *Int. Zschr. Vitaminforsch.* 2(36):133-136, 1966.

In 26 healthy individuals, 16 women and 10 men, 22 to 83 years old, of whom 20 were edentulous denture wearers, resting whole saliva, serum and urine samples were collected in the morning after overnight fasting. All sera were tested immediately but 4 saliva samples and all urine samples were kept overnight deep-frozen at -18°C . The assay of folic acid was accomplished by the microbiological method using *Lactobacillus casei*. Growth was determined by measurement of turbidity. The mean folic acid conc. of resting saliva were about 10 times the serum conc. and 5 times that of urine. As the correlation coefficients were small, it would seem that folic acid activities of serum or urine in healthy subjects cannot be assessed from the folic acid values of the saliva.

- 10847 POSTOPERATIVE RADIOMETRIC STUDIES OF GASTRIC pH IN PATIENTS WHO HAVE UNDERGONE GASTRIC RESECTION. (It.) Di Matteo, G. (U. Rome, Italy), F. P. Campana and F. Zechini. *Progr. Med. (Napoli)* 22(2):57-61, 1966.

Gastric acidity and pH response to stimulation were studied in 31 patients who had undergone gastric resection for duodenal ulcer 3 mo.-25 yr. before. Each received a single dose of histamine or an alcohol meal, following determination of fasting pH values. In patients operated 8-10 mo. before, fasting pH values oscillated within a narrow range, between 6 and 8; 2-3 yr. after resection, they oscillated between 5 and 7, with periodic decreases to pH 3-4. In patients seen more than 3 yr. post surgery, fasting pH levels had begun to stabilize or were effectively stabilized at 2-3. In all patients, histamine stimulation resulted in rapid reduction of pH to 2 or 3, completed within 1-2 hr.; stimulation by an alcohol meal induced a less rapid response, which was negligible 2-3 mo. post-operatively but which also resulted in final pH levels of 2-3 in patients seen after longer postoperative intervals. It is concluded that the stomach retains its ability to produce hydrochloric acid, even after extensive gastric resection, and that the resumption of this function depends primarily on the re-establishment of neural and humoral regulatory mechanisms.

- 10848 A QUANTITATIVE STATEMENT OF THE TWO-COMPONENT HYPOTHESIS OF GASTRIC SECRETION. (E.) Makhlof, G. M. (Western Gen. Hosp., Edinburgh, Scotland), J. P. A. McManus and W. I. Card. *Gastroenterology* 51(2):149-171, 1966.

Gastric juice collections were repeatedly made in 2 highly conditioned male subjects over a 20-mo. period. Salivary contamination was prevented by use of dental pledgets. Juice was collected every 5 min. Only 1 dose level of gastrin was studied in any one single session, infusion rates varied from 0.2 to 90 $\mu\text{g/hr}$. Acidity was determined by titration, sodium and potassium by flame photometer, and chloride, electrometrically. Spontaneous acid secretion was found to be 0.88 mEq/hr. and 1.35 mEq/hr. Volumes were approx. 25-30 ml/hr. Gastrin infusion showed a biphasic response, peak vol., acid and potassium output occurring approx. 40 min. after start of infusion followed by a near steady state. Sodium conc. was

inverse. Histamine produced peak acid output after 2 hr.; acid and sodium conc. varied inversely. Peak potassium conc. preceded acidity. The following were the steady state av. conc. following 1.4 $\mu\text{g/kg/hr.}$ gastrin for the 2 subjects: vol. 5 ml and 101.5 ml/20 min.; H 131.8 and 141.7 mEq/liter, Na 12.5 and 8; K 17.1 and 9; Cl 160.5 and 164.4. The highest Na conc. occurred during lowest secretory rates. Following gastrin Na output rose for 20 min. dependent on dose, then returned to resting levels in spite of the infusion. The constancy of Na output led to the conclusion that the nonparietal component is produced in fixed quantities. The equation $\text{Na} = \text{Na}_0 \cdot k/v$ (where Na = output, Na_0 = primary concentration of Na in nonparietal component, k = the rate that the nonparietal component is produced, v = the total vol. flow/unit time) was found to represent the findings. In similar fashion $\text{H} = \text{H}_0 - 1/v \cdot k \cdot (\text{H}_0 + b)$ (where H = acid output, H_0 = primary acid conc. in parietal component, b = primary conc. of bicarbonate ions in nonparietal component) was found to describe acidity. K and Cl output were described by the following equations: $\text{K} = \text{K}_p - 1/v \cdot k (\text{K}_p - \text{K}_{np})$; $\text{Cl}_{np} + b = \text{Na}_0 + \text{K}_{np}$ (where K_p = primary conc. of K in parietal component, K_{np} = K conc. in nonparietal component, Cl_{np} = primary conc. in nonparietal component. The experimental data were well represented by the equations. A preliminary estimate of the composition of the nonparietal component showed it to be similar to interstitial fluid. A second series of studies using similar technics studied electrolyte conc. and secretory rate during nonsteady state secretion, produced by single i.v. or s.c. doses of histamine or gastrin. Following inj. of gastrin peak output of acid and K occurred within 20 min., the conc. of Na and acid varied inversely. By the end of the 50 min. test Na rose to some of the highest levels measured. The highest acidities and lowest Na were found following histamine inj. Regression analyses of 56 single dose and 29 infusion experiments with gastrin of hydrogen ion conc. and electrolyte conc. data indicated the primary conc. of the components was independent of the means of stimulation; the conc. of electrolytes were linearly related and independent of collection time. Gastric juice was considered a variable mixture of 2 components in which various cellular products are dispersed. The parietal cells are responsible for secretion of HCl and KCl; the nonparietal component is identical in composition with interstitial fluid. The importance of Na output as an index of the nonparietal component was considered established.

49 THE EFFECT OF POTASSIUM DEFICIENCY AND OF STEROIDS ON GASTRIC AND RENAL HYDROGEN ION SECRETION. (E.) De Lange, W. E. (State U., Groningen, Netherlands) and H. Doorenbos. *Folia Med. Neerl.* 9(4):120-125, 1966. Gastric secretion was studied in pylorus-ligated rats for 4 hr. following inj. of histamine (approx. 10 mg/kg s.c.). Urine was collected for 6 hr. following inj. of ammonium chloride (approx. 10 mg/kg i.p.), and blood samples were collected by cardiac puncture at the end of both of the preceding studies. Animals were divided under each of these conditions after 4 wk. of the following procedures: 1) control diet, 2) potassium-deficient diet, 3) potassium-deficient diet and dexamethasone (DOC; approx. 2.5 mg/kg/day), 4) control diet with DOC triacetate (125 mg/kg, s.c.) on the first day, 5) control diet with prednisolone (2.5 mg/kg/day, i.p.), and 6) a potassium-deficient diet along with dexamethasone (same as above). Serum potassium fell progressively in Groups 1, 2, and 3 (Group 6 equaled Group 3), while Groups 4 and 5 were at control levels. The lowest gastric pH was found in Group 5. The pH increased progressively in Groups 1, 2, and 3 as vol. decreased. No differences were seen between urinary pH of Groups 1 and 4, 5 and 6; Groups 2, 3, 5 and 6 had a higher pH than Group 1. In some instances the admin. of ammonium chloride depressed blood pH and bicarbonate. The patients with primary aldosteronism and 2 with anorexia nervosa showed a diminished capacity to secrete hydrogen ions via the gastric mucosa and the renal tubules. In 2 patients, correction of the potassium depletion increased this capacity. It was concluded that potassium depletion diminishes the ability to establish a hydrogen ion gradient in the renal tubule and the gastric mucosa, an abnormality which may be accentuated in the presence of mineralocorticoid excess. Potassium depletion has no effect upon the capacity to secrete hydrogen ions when potassium depletion is prevented.

SECRETION

- 10850 ANALYSIS OF GASTRIC OXYNTIC FUNCTION, AS RELATED TO CHLORIDE RELEASE. (Rus.) Torosov, T. M. (S. M. Kirov Milit. Acad. Med., Leningrad, USSR). *Fiziol. Zhur. SSSR Sechenov* 52(5):521-524, 1966.
- In esophagotomized dogs with Bazov gastric fistulas and in 42 patients with acute or chronic dysentery, or acute gastroenterocolitis, a pronounced positive linear dependence was found between the amount of total chlorides and total acidity in the gastric juice. The coefficient of correlation was +0.774 in the dogs, +0.512 in acute dysentery, +0.575 in chronic dysentery, and +0.588 in gastroenterocolitis. The absolute value of acidity at a high chloride conc. in the 3 groups of patients was 41.8%, 54.5%, and 59.8%, resp., at a chloride conc. of 200 mEq/1000 ml compared to 92.6% in the dogs. This difference between experimental and clinical results was gradually decreased as total chloride conc. fell. In acute dysentery, the acidity was higher at lower total chloride conc., showing that the utilization of total chlorides in HCl synthesis was increased, although a general depression of acid formation was seen in acute dysentery. The total chloride conc. at the same level of acidity varied in different groups of patients; e.g., when total acid content was 65.66-66.95 ml, the total chloride conc. (in mEq/1000 ml) was 160.0 in acute dysentery, 130.0 in chronic dysentery, and 120.0 in gastroenterocolitis. The good correlation between the chloride conc. and the total acid vol. indicates the intensity of enzymatic processes at various stages of acid formation. Possible explanations for these data are discussed.
- 10851 EFFECT OF IN VIVO PANCREOZYMIN AND METHACHOLINE ON PANCREATIC LIPID METABOLISM. (E.) Webster, P. D. (Duke U. Med. Ctr., Durham, N. C.), L. D. Gunn and M. P. Tyor. *Am. J. Physiol.* 211(3):781-785, 1966.
- Pancreatic homogenates were prepared from pigeons treated with i.v. pancreozymin or i.m. methacholine, admin. either separately or together, and the rates of palmitate C14 oxidation and incorporation into triglyceride and phospholipid were measured. There was a definite increase in these measurements of pancreatic lipid metabolism following admin. of both agents, compared with saline-treated controls. Lipid metabolism in pigeon liver homogenates was not altered by either pancreozymin or methacholine; i.v. admin. of secretin had no effect on pancreatic lipid metabolism. It is concluded that pancreozymin and methacholine stimulate secretion of pancreatic digestive enzymes and act in some fashion to enhance pancreatic lipid metabolism; they may possibly have a primary or secondary effect on the thiokinase or long-chain fatty acid-activating system.
- 10852 COLD STABILITY OF LACTATE DEHYDROGENASE OF HUMAN GASTRIC JUICE. (E.) Fenton, B. H. (Roy. North Shore Hosp., Sydney, New South Wales, Australia) P. E. Baume and D. W. Piper. *Clin. Chim. Acta* 14(4):553, 1966.
- Lactate dehydrogenase (LDH) activity in gastric juice from 6 normal volunteers was measured immediately after collection; each sample was then divided into 4 portions and stored at 4° or -20° C; LDH activity was measured again after 1 and 7 days. Storage of neutralized gastric juice at 4° for 1 and 7 days was associated with preservation of $94.8 \pm 5.6\%$ and $88.5 \pm 7.1\%$, resp., of initial total LDH activity. However, storage at -20° for 1 and 7 days resulted in preservation of only $41.6 \pm 32.4\%$ and $39.3 \pm 24.2\%$, resp., of initial LDH activity. It is concluded that estimation of gastric juice LDH should ideally be made immediately on fresh specimens, but if storage is unavoidable, 4° is a suitable temperature at which LDH activity is fairly well preserved for up to 7 days.
- 10853 INTRAGASTRIC JEJUNAL IMPLANTS AS A BIOLOGIC INDICATOR OF ACID-PEPTIC ACTIVITY. EXPERIMENTAL MODEL USING GASTRIC FREEZING IN DOGS. (E.) Lippman, H. N. (Cedars-Sinai Med. Ctr., Los Angeles, Cal.), S. L. Michel, C. S. Patin and L. Morgenstern. *Am. Surg.* 32(10):709-711, 1966.
- In adult dogs, a segment of proximal jejunum measuring about 5 cm in length was transplanted into the anterior wall of the stomach midway between the incisura and the cardia. Ten control animals with such an implanted patch survived up to 6 mo. with no evidence of peptic ulceration of the patch. Ten other animals with histamine-induced gastric hypersecretion all died within 1 mo. from perforated peptic ulceration of the patch. Gastric freezing after jejunal patches had already been implanted into the stomach caused no differential damage or significant structural

ges in the patch, compared with adjacent gastric mucosa. In 43 animals with gas-patches undergoing gastric freezing before each daily histamine inj., av. survival time was 3 mo., some surviving as long as 5-6 mo.; this was in sharp contrast to rapid death of animals receiving histamine stimulation without prior gastric freezing. It is concluded that this technic is a sensitive biologic indicator of gastric acid-peptic activity, useful in studying problems of gastric physiology.

4 THE EFFECT OF HYPOPHYSECTOMY ON CANINE PANCREATIC FUNCTION. (E.) Tiscornia, O. M. (Mount Sinai Hosp., New York, N. Y.) and D. A. Dreiling. *Surgery* 60(4):883-890, 1966.

During the first 7 days after hypophysectomy, during maintenance treatment with ACTH, pancreatic flow rates, bicarbonate secretion rate, and amylase elaboration were decreased in 7 of 8 dogs. After abrupt withdrawal of ACTH, a statistically significant decrease in all of these parameters was seen, particularly in animals with complete hypophysectomies. Depression of all secretory parameters in hypophysectomized dogs were seen when ACTH was stopped, but reversed by resumption of treatment or a variety of adrenal steroids (cortisone, deoxycorticosterone acetate, or dexamethasone); it did not appear to be dependent upon secondary hyperparathyroidism or either thyroid function or serum electrolytes. It is postulated that posthypophysectomy suppression of enzyme and electrolyte secretion by the pancreas is mediated by the adrenals.

5 INHIBITORY EFFECT OF FAT IN THE DUODENUM AND UPPER SMALL INTESTINE ON EXOGENOUS GASTRIN-STIMULATED GASTRIC SECRETION. (E.) Bibler, D. D., Jr. (U. Washington Sch. Med., Seattle, Wash.), H. N. Harkins and L. M. Nyhus. *Surgery* 60(4):844-847, 1966.

Four dogs underwent formation of a Heidenhain pouch, resection of the remaining stomach including the antrum, esophagoduodenostomy, and insertion of an esophageal cannula. Gastrin was infused (2 mg/hr. for 12 experiments/dog); after a plateau of gastric secretion had been established, 45 ml of fat nonemulsified 100% corn oil were infused by gravity into the duodenum and proximal small intestine by a tube in the esophageal cannula. Acid production was decreased during the 2-hr. period immediately after corn oil infusion; inhibition began 15-30 min. after fat insertion, with the greatest depression occurring after 60 min. Within 2.5 hr., acid secretion returned to the plateau level. It is concluded that fat infusion inhibits gastric secretion at the parietal cell level.

6 INTERACTIONS BETWEEN CYTOCHROME SYSTEM AND H⁺ ION SECRETION IN BULLFROG GASTRIC MUCOSA. (E.) Kidder, G. W. III (U. Louisville Sch. Med., Louisville, Ky.), P. F. Curran and W. S. Rehm. *Am. J. Physiol.* 211(2):513-519, 1966.

Relationships between oxidation-reduction states of cytochrome and active hydrogen ion (H⁺) secretion were examined in isolated frog gastric mucosa, a tissue which contains a normal complement of cytochromes, flavoprotein, and nicotinamide adenine dinucleotide. Changes in the rate of H⁺ transport resulted in changes in the oxidation-reduction state of cytochrome c. The results suggested that acid secretion was closely associated with a process that caused cytochrome c to shift from a more reduced steady state. There was an apparent excess of cytochrome c in gastric mucosa relative to the amounts usually found in mitochondrial preparations; this suggests that there is extra-mitochondrial cytochrome c which may be specifically involved in the transfer of energy and H⁺.

7 ZINC 65 METABOLISM: GASTROINTESTINAL SECRETION BY THE PIG. (E.) Pekas, J. C. (U. Tennessee, Oak Ridge). *Am. J. Physiol.* 211(2):407-413, 1966.

Pigs receiving a single i.v. inj. of Zn⁶⁵ (1 mc), 96% of the dose was excreted in feces within a half-time of 100 days, the remainder with a half-time of about 3 days; fecal excretion accounted for 75-90% of the total Zn⁶⁵ excreted. Pancreatic duct ligation or total fistulas of the pancreas and gallbladder, or of a 40-cm segment of duodenum did not appreciably decrease fecal Zn⁶⁵ excretion. A total 4-day collection of pancreatic juice and bile and a 5-day collection of duodenal juice accounted for 0.05%, 0.055% and 0.150%, resp., of the total Zn⁶⁵ dose. Secretion of Zn⁶⁵ in

SECRETION

pancreatic juice was closely associated with total protein secretion; it is suggested that a specific pancreatic secretory cycle exists for zinc secretion. The behavior of Zn^{65} in blood fractions was similar to that of other species (dog, rat, rabbit, or man).

- 10858 FASTING GASTRIC CONTENTS IN CONSCIOUS Macaca mulatta. (E.) Smith, G. P. (U. Pennsylvania Sch. Med., Philadelphia), J. W. Mason and E. D. Jacobson. Am. J. Physiol. 211(3):629-633, 1966.

In immobilized, fasted rhesus monkeys (Macaca mulatta) with chronic gastric fistulae, the gastric contents contained significant amounts of acid ($pH\ 1.9 \pm 0.5$, acid conc. 49.2 ± 31.6 mEq/liter, and acid output 0.21 ± 0.09 mEq/30 min.). The gastric contents of unrestrained animals in their home cages had similar mean values for pH (1.8) and acid conc. (41.8 mEq/liter). Fasting gastric acid secretion was markedly inhibited by i.v. inj. of atropine (12.5 μ g/kg or more) or i.v. infusion of norepinephrine (1-3 μ g/kg/min.); the same i.v. doses of norepinephrine also inhibited gastric secretion produced by submax. histamine stimulation.

- 10859 RAT GASTRIC ACID SECRETION IN RESPONSE TO GRADED SUBCUTANEOUS DOSES ON 2-DEOXY-D-GLUCOSE. (E.) Baume, P. E. (Roy. North Shore Hosp., Sydney, New South Wales, Australia), A. Nicholls, R. A. Barnett and R. A. Room. Am. J. Physiol. 211(3):626-628, 1966.

In pylorus-ligated rats, gastric acid secretion was stimulated following single i.v. of the vagal stimulant 2-deoxy-D-glucose (0-800 mg/kg s.c.), the effect of the agent over a 4-hr. period being to increase the vol. instead of the acidity of gastric juice. The max. secretion was seen at 600 mg/kg; acid secretion was absent at the highest dose, possibly as a result of in vivo inhibition of gastric mucosa. At 0-2 or 3-4 hr. after treatment a stimulation was seen; the max. gastric secretory response was seen 3-4 hr. after treatment, although a significant response was noted at 0-2 hr. (in contrast to the effect of histamine).

- 10860 TRYPSIN AND CHYMOTRYPSIN SECRETION FROM RABBIT PANCREAS IN VITRO. (E.) Rothman, S. S. (Harvard Med. Sch., Boston, Mass.). Am. J. Physiol. 211(3):777-780, 1966.

Chymotrypsin and trypsin activity in vitro and in vivo was studied in rabbit pancreas preparations. Enzyme activity in collected secretions was observed for as long as 12 hr. after mounting in vitro without metabolic or synthetic substrate present, but enzyme activation (with enterokinase) was necessary for the demonstration of both tryptic and chymotryptic activity. The mean value for enzyme output was less in vitro than in vivo, but a great overlap was observed between the 2 populations. The trypsin:chymotrypsin ratios in vitro were only slightly lower than the in vivo ratios; in all observations trypsin was more abundant than chymotrypsin. Pancreozymin and methacholine chloride augmented enzyme output in vitro, independent of water secretion. The stability of the trypsin:chymotrypsin ratio for in vitro secretion as well as the capability of measuring the gland's entire enzyme output for short intervals suggests that this system may prove useful for the study of the mechanism of synthesis, intracellular translocation, and secretion of the enzymes.

- 10861 EFFECTS OF SOME ADRENERGIC BLOCKING AGENTS ON GASTRIC SECRETION IN DOGS. (E.) Pradhan, S. N. (Howard U. Coll. Med., Washington, D. C.) and H. W. Wingate. Arch. Int. Pharmacodyn. 162(2):303-310, 1966.

Gastric secretion was studied in 6 dogs with Necheles fundus pouches and 2 with whole stomach gastric fistulae. Phentolamine (0.12 mg/kg i.v. and 1.2 mg/kg i.p.) and tolazoline (0.6 and 1.2 mg/kg i.p.) induced secretion. Phenoxybenzamine (Dibenzylamine; DBZ; 20 mg/kg i.p.) and dichlorisoproterenol (DCI; 10 mg/kg i.p.) failed to induce secretion and were used for further experiments. DBZ (20-30 mg/kg) and DCI (10-20 mg/kg), 30 min. prior to feeding, completely inhibited food-induced gastric secretion for approx. 2 hr. in 4 dogs. DBZ blocked bethanechol (75 and 150 μ g/kg)-induced secretion in 1 of 2 dogs tested at 15-20 mg/kg doses. DCI blocked bethanechol following an i.v. dose of 7 mg/kg or an i.p. dose of 10-20 mg/kg in 9 experiments with 2 dogs. Both DBZ (15-20 mg/kg) and DCI (3-6 mg/kg i.v.

EXCRETION

10 mg/kg i.p.) reduced the vol. and acidity of histamine (25 mg/kg)-induced gastric secretion. The effect of DBI was studied in 6 experiments with dogs on gastric secretion induced by simultaneous admin. of 1000 mg epinephrine, by bethanidine 10 mg, or by isoproterenol 1 mg and by histamine with isoproterenol. No definite conclusion can be drawn, however, partial blockade of adrenergic inhibition of secretion was observed in 2 cases. When DBI was tested in similar combinations, a partial blockade of adrenergic inhibition of secretion was seen in 1 experiment with bethanidine and in 3 experiments with isoproterenol. It was concluded that adrenergic inhibition of gastric secretion is mainly a β -receptor function; however, a dual receptor influence cannot be ruled out. It would seem a preponderance of α -receptor activity needs to be emphasized.

100. HYPERCALCEMIA AND GASTRIC SECRETION IN MAN. L. J. Murphy, Jr. (UCLA, California), R. J. Heath, Jr., D. Angeles, R. G. Gosselin, and J. W. Warr. Am. J. Physiol. 216:1637-1641, 1968.

Gastric acid secretion was determined in 8 patients (3 with duodenal ulcer, 5 with gastric ulcer, 2 with alcoholic gastritis, and 1 with gastric cancer) by basal, following admin. of betazole (10 mg/kg). On some days, basal secretion was reduced to 1 ml, after which an infusion of either saline or 100 mg of calcium gluconate (10 mg/kg calcium gluconate over 1 hr) was started. Each patient received both calcium and saline infusions. Serum calcium was determined every 30 min. Gastric acid increased during calcium infusion in all 8 subjects; the peak calcium-stimulated acid secretion was 20% of the peak effect following betazole. The effect of calcium infusion continued to 1 hr after its cessation. The effect of calcium infusion on serum calcium was increased by 3.4% (mean 100 mEq/l) in 6 patients. These effects were similar to those suggested that the effects measured are mediated either through release of gastrin or through an increased adrenergic effect mediated by hypercalcemia, which might be due to vagal stimulation, increased acetylcholine release, or to increased sensitivity of the parietal cell to acetylcholine.

100. EXCRETION OF TOTAL SOLUTE, SODIUM AND POTASSIUM IN THE SALIVA OF THE RAT PAROTID GLAND. (E. Mangos, J. - (Physiol. Inst., Free L. Berlin, Germany) and G. Brauer. Pflüger's Arch. Ges. Physiol. 290(2):184-19, 1968.

Saliva was collected to 30-60 min. in the resting state from anesthetized male Sprague-Dawley rats in polyethylene tubes (50 μ l) introduced into the right parotid duct by a small incision. The volume could be determined by examining the length of the fluid in the tube under a microscope. At higher secretory rates samples were collected through a 60-80 μ l diameter tube in the duct. In all 190 samples were collected from 24 rats. Pilocarpine (0.1 mg/10 g) was given i.p. Ouabain (10^{-4} M) was injected retrograde through the collection tube, using a dye marker, until it entered the intercalated duct region, and was kept there for 1.5-2 min. Osmolality and sodium and potassium conc. were determined in each sample. Saliva was isotonic to plasma at resting flow rates; a slightly increased flow resulted in decrease in osmolality (to 86 mOsm/l) but a further increase in flow increased osmolality toward isotonicity. These changes were mainly due to sodium conc. Potassium conc. was 3-4 times plasma levels and did not vary with flow rates. Ouabain or retrograde flow did not affect the flow rate but osmolality and sodium conc. were increased. It is concluded that the rat parotid gland is similar to that of man and dog in secretion of water and electrolytes. The data support the hypothesis that parotid saliva is formed by secretion of a plasma-like fluid in the acini-intercalated duct region, which is subsequently modified by active sodium resorption in excess of water in another site (or sites) of the duct system of the gland.

864 THE EFFECTS OF ESTROGEN AND PROGESTERONE ON THE VISCOSITY OF CANINE SALIVA. (L.) Dworkin, B. F. (Michael Reese Hosp., Chicago, Ill.), R. Mendelsohn and A. Wolach. J. Pediatr. 69(2):287-289, 1966.

male and 2 female dogs (not in estrus) were conditioned to salivate upon presentation of a plastic bottle of lemon juice. Collection of mixed salivary

SECRETION

secretions were made 30 min. after admin. of progesterone (100 mg p.o.); immediately after collection, viscosities were determined. In 5 experiments, the viscosity increased markedly for several hr. after progesterone admin. This increase was attenuated by concurrent admin. of conjugated estrogen (20 mg i.m.) or estrone (8 mg i.m.) in 3 experiments. Since estrogen alone produced an increase in viscosity, estrogen and progesterone appeared to have a mutually inhibitory effect.

- 10865 RESEARCH ON THE SECRETION OF MUCUS BY AN ISOLATED SEGMENT OF COLON IN THE DOMESTIC RABBIT. (Fr.) Bonnafoous, R. (Inst. Physiol., Toulouse, France) and P. Raynaud. *Arch. Sci. Physiol. (Paris)* 20(2):181-187, 1966.

Isolated (5-6 cm) portions of rabbit colon with an intact vascular supply were studied. Antibiotics were admin. during the experiment; intestinal washings were collected at 12-hr. intervals over 8 days. Only clear, viscous samples were taken. Only 5 of the 40 animals operated survived, and by the end of the experiment only 2 regained full vitality. Fecal nitrogen excretion was greater in the night (mean 72.6 mg/g dry wt.) than in the daytime (mean 68.8 mg/g); total nitrogen excretion was also greater during the night (2.62 mg, compared to 1.772 mg in 1 animal) in all 5 animals. During this time, the isolated segment might be the site of partial and selective reabsorption of the constitutive elements of the secreted mucus. A mucinase (as found in other species) may be present; humoral factors might also influence the differences noted.

- 10866 RELATIONSHIPS BETWEEN BILIO-DUODENAL DISCHARGE AND PANCREATIC FUNCTION. (It.) Stefanini, P. (U. Rome, Italy) and M. Ermini. *Minerva Med.* 57(31):1394-1403, 1966.

Ligation of the common bile duct and cholecystoenterostomy were performed in 5 dogs to allow for duodenal content studies to be made (every 10 days for 3 mo.) in the absence of bile. Blood glucose levels fell irregularly until day 80, then were stabilized at about 50% of the original levels (1.05 g% to 0.55 g%). Glucose tolerance tests could not be interpreted because of great variability. Blood glucose increased gradually until the third sampling (45 min. after glucose inj.) but returned to normal levels thereafter, suggesting endocrine hyperactivity. Alloxan inj. (60-70 mg/kg) resulted in a severe diabetes, reflected in an increased blood glucose conc. (0.50-0.80 g%). Serum and duodenal amylase levels increased progressively but variably from day 10, and were stabilized at 200% of control levels 2 mo. after initial intervention. Trypsin levels rose from 8-23 g%. These findings indicated exocrine hyperactivity, which was balanced at an elevated level after 60 days. Morphological changes coincided with the described functional changes; acinar hyperactivity was indicated by increased numbers of zymogen granules and increased islet tissue. Five patients with pancreatic dysfunctions (such as pancreas cancer or chronic pancreatitis) showed similar changes after creation of various fistulas.

- 10867 STARTING MECHANISMS OF INTESTINAL SECRETION. (Rus.) Tambovtsev, A. N. (Inst. Pedagogy, Omsk, USSR). *Biull. Eksp. Biol. Med.* 61(6):19-22, 1966.

Intestinal juice secretion was studied in dogs with isolated jejunal segments (Thiry-Pavlov method). After feeding meat, secretion increased in the first 4 hr.; after feeding bread, it increased after 3-4 hr.; feeding of milk resulted in a gradual increase in secretion, to a peak after about 4 hr. Simulated feeding of meat increased secretion in the first and (to a lesser extent) second hr.; under these conditions, secretion was increased in the first hr. only with bread, and gradually increased in the first 3 hr. with milk. Intestinal secretion was also stimulated by a bell in dogs with conditioned reflexes. Secretion was increased in the first 15 min. after simulated feeding in esophagectomized dogs, but decreased thereafter. Stimulation of secretion was abolished by vagectomy; electrical stimulation of the vagus nerve stimulated secretion, while stimulation of the peripheral and splanchnic nerves inhibited it. It is concluded that intestinal juice secretion is initiated by conditioned (cortical) reflexes and by the effect of food on the oral cavity receptors (unconditioned reflex).

- 10868 EFFECTS OF PORTACAVAL SHUNT ON GASTRIC SECRETION IN CIRRHOTIC DOGS. (It.) Storace, R. (U. Bologna, Italy). Chir. Pat. Sper. 13(5-6):178-182, 1965.

Mature mongrel dogs bearing a Heidenhain fistula were rendered cirrhotic by treatment with carbon tetrachloride, prior to establishing a portacaval anastomosis and return to normal diet. Each dog served as its own control for measurements of gastric secretion prior to liver damage, following development of cirrhosis and following creation of the shunt. Statistically significant increases of gastric secretion followed the induction of liver cirrhosis, while the cirrhotic levels thus established were increased by 200% to more than 500%, following creation of the shunt. This second increase was accompanied by increased liver parenchymal damage, confirmed at necropsy; a decrease of serum albumin levels; and a transient decrease, followed by an abrupt and very marked increase, of serum alkaline phosphatase activity. It is concluded that the portal venous blood bypassing the liver appeared to contain an activator of gastric secretion whose action is normally inhibited by the liver, with a significant degree of inhibition still evidenced in the presence of extensive cirrhotic changes.

- 0869 ELECTROGENIC MECHANISMS OF THE FROG'S GASTRIC MUCOSA. (E.) Rehm, W. S. (U. Alabama Med. Ctr., Birmingham). Ann. N. Y. Acad. Sci. 137(2):591-605, 1966.

Frog gastric mucosa stripped of external muscle layers was mounted in a special double chamber organ bath allowing the measurement of potential difference (PD) and passing a current through the preparation. H^+ secretory rate was measured. With Cl^- -free media the PD was inverted, the nutrient side being negative. Sulfate media and procedures that reduced H^+ secretion also abolished the inverted PD. H^+ secretory rate after DNP inhibition varied linearly with PD. The av. electromotive force of the H^+ mechanism was estimated to be 44 mV and the av. resistance 920 ohm/cm². Removal of external K^+ reduced H^+ rate to zero with only small changes in mucosal pH . Addition of K^+ to the secretory fluid restored secretion. A scheme was presented to account for the characteristics of the secretory mechanism and the ionic composition of the tubular cells of the mucosa. The scheme has an electrogenic Cl^- and H^+ mechanism on the lumen side and a mechanism to conc. K^+ in intracellular compartments. It does not possess a mechanism of K^+-Na^+ exchange at the cellular border.

- 0870 THE EFFECT OF ALLOXAN ON GASTRIC SECRETION. (E.) Caridis, D. T. (U. Aberdeen, Scotland), D. W. Blair, S. J. Kilpatrick and A. J. Carr. Scot. Med. J. 11(7):247-249, 1966.

Male rats made diabetic by i.p. admin. of alloxan monohydrate (100 mg/kg every other day, total dose 125 mg) were subjected to pylorus ligation for the collection of gastric secretions. Confirmation of the diabetic state was by elevated fasting blood sugar, glycosuria and acetonuria. Gastric juice was collected over a 4-hr. period. There was a marked diminution in acid secretion in alloxan-treated diabetic rats ($N=23$) 0.14 mEq, when compared to controls ($N=29$) 0.279 mEq. In the alloxan-treated nondiabetic rats the acid level was between those of the other two groups. There were no differences either macroscopically or histologically between the stomachs of the 3 groups. Only the beta cells in the islets of Langerhans in the diabetic rats were completely destroyed; the alpha cells were normal. There was no difference in acidity in rats fed 5% glucose in their diet, a control for alloxan-treated rats receiving glucose in their diet. It is suggested that the inhibitory effect of alloxan on secretion of acid from the gastric mucosa in rats is a result purely of the elevation of the blood sugar following selective destruction of the beta cells of the islets of Langerhans.

- 0871 A GASTRIC PHASE OF PANCREATIC SECRETION. (E.) Blair, E. L. (U. Newcastle upon Tyne, England), J. C. Brown, A. A. Harper and T. Sctacherd. J. Physiol. (London) 184(4):812-824, 1966.

Experiments were performed on anesthetized cats. The pancreatic duct was cannulated, ureter was inj. to maintain the flow of pancreatic juice. The stomach was divided into 2 parts at the junction of the body and antrum by ligation around a

SECRETION

plastic cylinder and the 2 parts were drained separately through inserted soft rubber tubes. The pylorus was also ligated. The 2 "pouches" were inflated by inflation of balloons, or inj. of various soln. Normally the body stomach was filled with glycine soln. which was periodically drained and analyzed. Extracts of antral mucosa increased pancreatic amylase output, and had a slight secretin-like effect on a pancreas already responding to endogenous or exogenous secretin. Instillation of meat extracts or acetylcholine soln. into the antrum in cats with the vagus and splanchnics cut stimulated secretion of gastric acid and pancreatic amylase. These effects were blocked by atropine or cocaine of the antrum. In animals with the vagus intact, distention of the body or antrum increased amylase. Vagal section blocked the effect of body distention only. It is concluded that there is a gastric phase of pancreatic secretion which is almost entirely a stimulation of enzyme output. The vago-vagal pathway is required for the response to distention of the body. The effects of atropine and cocaine on the response to stimulation of the antrum suggest that the release of the antral stimulant depends on a local cholinergic reflex pathway in the antrum.

- 10872 **INTESTINAL FACTORS AFFECTING PANCREATIC EXOCRINE SECRETION IN THE RAT.** (E.) Ramirez, J. (U. Iowa Coll. Med., Iowa City), K. A. Hubel and J. A. Clifton. Am. J. Physiol. 211(1):260-263, 1966.

Pancreatic secretions were collected in anesthetized rats by cannulation of the distal bile duct; the common bile duct was ligated; bile was diverted by a catheter into the second portion of the duodenum. The duodenum was perfused through an inlet cannula inserted into the pylorus; the collecting cannula was inserted into the jejunum (1-1.5 cm was perfused). Lower segments were perfused by similar placements lower down the intestine. Perfusion of the duodenum or upper jejunum with isotonic soln. of glucose, methionine, or sodium oleate had no effect on flow or protein conc. of pancreatic juice. Perfusion of duodenum with HCl increased flow rate and reduced protein conc. of pancreatic juice. Perfusion of 6 cm jejunal segments indicated peak flow rate decreased in the caudal segments--perfusion of segments more than 10 cm below the ligament of Treitz had no effect on secretory rates. It is concluded that the secretin mechanism is present in the rat and that the quantities of secretin present in the intestinal mucosa decrease caudally.

- 10873 **OPERATIVE PROCEDURE FOR RESECTION OF INTESTINAL MUCOUS MEMBRANE IN CHRONIC EXPERIMENTS.** (Rus.) Kurtsin, J. T. and V. K. Bolondinski. Fiziol. Zhur. SSSR Sechenov. 52(1):112-113, 1966.

A modified Thiry-Vella method of resection of the intestinal mucous membrane in dogs is presented. An intestinal segment (15 cm long) 10-20 cm from the duodenal end was excised so that its mesentery was preserved. Before this step, serous-muscular pouch sutures were made and tightened in the ends of the segment. Continuity of the intestine was restored by enteroenterostomosis. The excised intestinal segment was taken out; the muscles and aponeurosis were sutured from both sides so that an opening remained in the center for the passage of the mesentery of the intestinal segment. The abdominal skin on all sides of the resection was peeled back to form a cutaneous pouch; a part of the intestine was then cut lengthwise along the side of the intestine across the mesenterial opening. The rectangular intestinal segment obtained was sutured initially at the corners of the flap to the subcutaneous tissue. The walls of the other flattened flap were sutured at the front and back with single sutures to the subcutaneous tissue so that the skin overlay the intestinal mucosa by 1-2 cm. From 1-2 wk. later the sutured intestine contracted normally. The RNA and DNA content in the intestinal mucosa of operated dogs ranged from 51.94-53.33 mg% and 39.2-41.03 mg%, resp. This method could also be used for the exposure of the stomach on the abdominal surface.

- 10886 EFFECTS OF THYROXINE ON SILKY AMYLASE OF THE RAT. (It.) Brighenti, L. (U. Ferrara, Italy) and L. Passerini. Boll. Soc. Ital. Biol. Sper. 42(6):304-305, 1966.

Following s.c. admin. of thyroxine (0.15-4.0 mg/100 g s.c.) to male rats, serum blood samples were taken and subjected to the silky amylase determination method of Bernfeld (using 3,5-dinitrosalicylate with a temperature modification of 5° C). Enzymatic activity was increased at 2.4 mg/100 g and below, while 3.2 mg/100 g and above resulted in normal or reduced activity. This behavior was similar to that observed during spleen and liver homogenate protein synthesis in animals treated with thyroxine, and was related to the enzyme level found in liver cells producing the enzyme.

- 10887 INVESTIGATION INTO THE DIGESTIBILITY OF PROTEIN FROM ANIMAL AND VEGETABLE SOURCES, WITH AND WITHOUT ADDITIONAL FAT. II. THE PASSAGE THROUGH SMALL AND LARGE INTESTINE. (Ger.) Canzler, H. (Max Planck Inst., Dortmund, Germany) and H. Glatzel. Nutr. Dieta. (Basel) 8(2):88-99, 1966.

X-ray studies showed that food of vegetable origin stimulates gastric juice secretion to a higher extent, at the same time passing through the stomach at a slower rate than food of animal origin. Addition of fat to vegetable food did not change the situation; added to animal diet, gastric juice secretion was only slightly enhanced and passage through the stomach only slightly prolonged. In the subsequent phase of gastric digestion, the origin of food (vegetable or animal) had no effect on the speed of passage. Regardless of origin, fatty meals were passed more slowly from the stomach. X-ray studies on jejunum, ileum, and colon passage made in 6 subjects who received test meals of identical vol. and identical protein and carbohydrate content, but different as to origin of protein and of varying fat content, showed that meals with vegetable protein, irrespective of fat content, pass more quickly through the jejunum and colon than those with animal protein. This did not apply to passage through the ileum; the colon was reached within about 3 hr. Addition of fat only slightly lengthened the passage of test meals through the jejunum but had no effect on the rate of passage through the ileum and colon. A clear mucosal outline in the X-rays appeared much earlier in subjects fed animal protein (regardless of the meal's fat content), suggestive that such food was fully absorbed in the jejunum; only contrast medium seemed to be reaching the lower tract. The above-mentioned quick passage of test meals containing vegetable protein was attributed to the larger proportion of indigestible fractions found in these meals.

- 10888 COMPARATIVE INHIBITION OF MAMMALIAN AMYLASES BY GOAT ANTISERA TO HOG PANCREATIC AMYLASE. (E.) McGeachin, R. L. (U. Louisville Sch. Med., Ky. W. M. Pavord, D. N. Widmer and P. A. Prell. Comp. Biochem. Physiol. 18(4):767-772, 1966.

Anti-hog pancreatic amylase antibodies were determined in the sera of goats treated with purified hog pancreatic amylase (25 mg, then 10 mg every 7-10 days s.c. for 4 mo.). The production of serum antibodies was somewhat different from the pattern observed in rabbits; the max. inhibition produced by goat antisera was 80-85%, compared to 95% with rabbit antisera. Peak amylase inhibition levels were seen within 2 mo. in goats, although antibody levels increased subsequently as shown by serial dilution studies. Pretreatment sera did not inactivate the enzyme. These antisera also had some degree of inhibitory activity (34%) against hog liver amylase. The goat antisera was strongly inhibitory to antigens of guinea pig and rabbit origin, appreciably inhibitory to amylase of human, rat, mouse and cat origin, less inhibitory to dog amylase and inactive against snake amylase. Endogenous serum amylase levels in the goats was low.

- 10889 PROTEOLYTIC AND PEPTIDASE ACTIVITIES OF THE JEJUNUM AND ILEUM OF THE RAT DURING POSTNATAL DEVELOPMENT. (E.) Noack, R. (Inst. Physiol., Czech. Acad. Sci., Prague), O. Koldovský, M. Friedrich, A. Heringová, V. Jirsova and G. Schenk. Biochem. J. 100(3):775-778, 1966.

The proteolytic and peptidase activities of the jejunum and ileum were studied in

GESTION

rats 7-60 days after birth, weaned at age 30 days and fed a standard diet thereafter. Proteolytic activity was substantially unchanged in the jejunum at age 7-21 days, but after 21 days a significant increase was observed. Enzyme activity in the ileum changed very little during postnatal life with respect to hydrolysis of protein, and was always greater than that of the jejunum. Tripeptidase activity was low in the jejunum at age 7 and 14 days; an increase was observed between 14 and 21 days, but later no substantial changes were observed. No changes occurred in the ileum. Prior to 14 days, the jejunum had less activity than the ileum, but enzyme activity was lower in the ileum thereafter. Aminopeptidase activity (using leucyl- β -naphthylamide as substrate) was low in the jejunum of 7- and 14-day-old rats, reached a peak at 21 days, and decreased thereafter, although the value at 60 days was still greater than at 7 and 10 days. Ileal activity was uniform throughout, except for a transient peak at 14 and 21 days. Jejunal activity was lower than ileal activity until about day 17, when the jejunal activity surpassed the ileal activity.

890 FATTY FOODS AND DYSPEPSIA. (E.) Taggart, D. (Prince Henry Hosp., New South Wales, Australia) and B. P. Billington. Lancet 2(7461):464-466, 1966. Twelve patients with digestive disorders attributed to foods fried or baked in fat were tested 6 times with a standard meal containing 28 g of fat, disguised so that it was not recognizable; both butterfat and oxidized fat (beef dripping) were used. Following the test meal, dyspeptic symptoms appeared in only 8% of the cases. No significant difference was found between butterfat and oxidized beef dripping in the production of symptoms. It is concluded that dyspepsia after fatty foods does not seem to be related to domestic or personal disturbances at the time of eating, to prejudice about fat. The results also indicate that the validity of other food intolerances can be investigated, if techniques of disguising flavor and other sensory characteristics of food can be found to allow a double-blind trial to be undertaken.

891 THE PROTEIN-POLYSACCHARIDE LINKAGE IN DOG SUBMAXILLARY MUCIN. (E.) Castellani, A. A. (U. Pavia, Italy), L. Zonta, C. Balduini and G. Pallavicini. Ital. J. Biochem. 14(6):378-387, 1966. Mucoprotein from dog submaxillary glands was composed of a carbohydrate portion (20%) containing galactose, fucose, acetylglucosamine, acetylgalactosamine, sialic acid, and sulfur, and a peptide portion (80%) which contained mainly threonine, serine, proline, glycine and alanine, together with small amounts of other amino acids. The infrared spectrum of the mucoprotein showed bands at 1220 cm^{-1} and at 1050 cm^{-1} due to -SO and -COS groups, suggesting that sulfur is present as the sulfate anion with an ester linkage to a hydroxyl grouping of the carbohydrate portion of the molecule. After reduction of the mucoprotein, no ester linkage was found between the carboxyl groups of the dicarboxylic amino acids and the hydroxyl groups of the monosaccharides, as reported for other mucins. Alkali treatment of the mucoprotein with simultaneous catalytic hydrogenation of the unsaturated products led to the conclusion that the linkage of carbohydrate and peptide portions is through the glycosidic linkages of the hydroxyl groups of serine and threonine to N-acetylglucosamine and N-acetylgalactosamine. Partial hydrolysis of the mucoprotein showed that the sialic acid, fucose, and galactose were easily detached and dialyzed, whereas the amino sugars were more strongly attached to the peptide core and probably involved in linkages with the hydroxyl groups of serine and threonine.

892 EFFECT OF DIETARY SODIUM CHOLATE AND LACTOSE ON THE FECAL MICROFLORA AND BLOOD CHOLESTEROL OF RATS. (E.) Graber, C. D. (Baylor U. Coll. Med., Houston, Texas), R. M. O'Neal and E. R. Rabin. Gastroenterology 51(3):357-363, 1966.

Bacterial counts and plasma cholesterol levels were measured in rats fed a standard diet or 3 experimental atherogenic diets (for 3 mo.): (1) 65% lactose; (2) sucrose with cholesterol and sodium cholate or (3) 40% butter with cholesterol and sodium cholate. About every 2 wk., the sodium cholate conc. was increased by (max. 8%) in Groups 2 and 3. After 12 wk., hypercholesterolemia was seen only in Group 3. Bacterial flora was not greatly altered by any of the diets; aerobes outnumbered anaerobes in all dietary groups. Lactobacilli were no more numerous in

DIGESTION

Group 1 than in controls. Clostridium perfringens recovery increased about 1000-fold in Groups 2 and 3, as compared to controls. However, since these animals had markedly increased cholesterol levels (up to 10-fold) but only negligible differences in C. perfringens isolations, there was no apparent role for this organism in the observed hypercholesterolemia. Sodium cholate, which seemed to increase recovery of C. perfringens, was the only dietary factor affecting bacterial flora. Butter was the one factor that seemed to determine the occurrence of hypercholesterolemia.

10893 RESPIRATORY HYDROGEN AND METHANE AS AFFECTED BY CONSUMPTION OF GAS-FORMING FOODS (E.) Caloway, L. P. (U. California, Berkeley). Gastroenterology 5 (5):383-389, 1966.

21 subjects were rec. for 3 successive wk. on alternate days, a control breakfast or one containing test foods (canned dried beans or fried onions), which are believed to produce hydrogen and methane in the intestinal tract. Levels of these gases were measured in breath samples collected before the 8 A.M. meal and every hr. from 10 A.M. through 4 P.M. About 3-4 hr. after eating beans there was a sharp rise in breath hydrogen content; peak levels were reached after 5-7 hr., when gas production was noted by the subjects. Breath hydrogen content after consumption of onions was not different in some subjects from that found after a control breakfast; in others, values were elevated, but less so than with the bean diet. The conc. of methane in breath was characteristic of the individual and did not vary much throughout the day or in response to food consumed. The significance of these findings is discussed.

- 894 TYRAMINE-RESISTANT ADRENERGIC MECHANISMS IN THE CARDIA OF THE RABBIT. (Ger.) Wolner, E. (U. Vienna, Austria) and F. Brücke. Naunyn Schmiedeberg. Arch. Exp. Path. 254(2):91-100, 1966.

The cardiac sphincter spasm of 18 rabbits under Nembutal anesthesia (35 mg/kg, with additional 3-5 mg/kg inj. every 2 hr.) was tested for the response to tyramine (1.0 mg/kg i.v. or 1.0 μ g/kg/min. by infusion). Norepinephrine followed by vagotomy preceded the i.v. inj. of tyramine. Some animals received reserpine (2.5 mg/kg) 48 hr. before the beginning of infusion, with another 1.5 mg/kg (i.m.) 24 hr. before infusion. Tyramine alone, even in doses of 4.0 mg/kg, had no effect on the sphincter spasm produced by bilateral vagotomy. If vagotomy was preceded by norepinephrine infusion for 2-3 hr. (max. 120-180 μ g/kg), 1.0 mg/kg i.v. of tyramine produced a 10% decrease of the spasm at 2.5 hr. and a 20% decrease at 3 hr. Norepinephrine infusion had to be interrupted at this point, beyond which the infusion becomes fatal to normal rabbits. In reserpinized rabbits, which tolerated norepinephrine infusion for over 7 hr., the relaxing effect of tyramine was considerably stronger than in normal rabbits, but it was ineffective when norepinephrine was not being infused. In both groups the tyramine effect appeared only after a minimum of 2 hr. of norepinephrine infusion, (20-30-second lag period after i.v. inj.), and lasted about 3 min. A definite correlation between duration of infusion and strength of the tyramine effect could not be established in the reserpinized group (30% relaxation at 2 hr., increasing nearly to over 90% at 7 hr.). However, repeated tyramine inj., admin. to reserpinized rabbits after 7 hr. of norepinephrine infusion and vagotomy (beginning 5 min. after vagotomy and at 5-min. intervals), became less and less effective, this decrease going parallel with the gradual drop in the animal's blood pressure (about 90 mm Hg at the first inj. to about 10 mm Hg after 7 inj., 40 min. later), and inversely proportional to the length of the lag period (20 seconds at first inj., 10 seconds at 6 inj.).

- 895 STUDIES ON THE GASTROINTESTINAL PASSAGE OF Au¹⁹⁸ COLLOID WITH THE SCINTILLATION CAMERA. (Ger.) Georgi, P. (Robert-Rössle Clin., Berlin), H.-J. Altenbrunn, J. Setka and H.-J. Gutz. Nuclearmedizin 5(3):246-249, 1966.

The speed of gastrointestinal passage was measured with a scintillation camera by pictures taken at 30-min. intervals after p.o. admin. of colloidal Au¹⁹⁸ (120-200 μ Ci in 50 ml water) to 15 normal subjects, 6 partially gastrectomized patients, and 6 totally gastrectomized patients. The av. time of passage was 160, 120, and 150 min., resp. Four other patients were treated simultaneously with Au¹⁹⁸ (200 μ Ci) and a 100-ml barium meal, which decreased the passage time in all cases. While the results are inconclusive, the use of scintillation cameras with exposure of the small intestine to not more than 250 mrad of irradiation (under the above conditions) is preferable to scintillation scanning which necessitates doses of 500-800 mrad of Au¹⁹⁸.

- 896 SIMPLE METHOD OF RECORDING QUANTITATIVELY CERTAIN GASTROINTESTINAL MOTILITY FUNCTIONS IN THE RAT. (E.) Derblom, H. (Academic Hosp., Uppsala, Sweden), H. Johansson and G. Nylander. Acta Chir. Scand. 132(1/2):154-165, 1966.

Marker soln. consisting of glucose (1 mg/ml), phenol red (1 mg/ml), 5% polyethylene glycol and of Cr⁵¹O₄Na₂ and phosphate buffer (10 μ Ci/ml) was admin. p.o. during ether anesthesia to 116 fasted rats. The radioactivity of the entire tract, and of the stomach and intestine separately, was determined 15-60 min. later with scintillation counter and planimetric analysis, with substantially identical results. Under these conditions, 40% of the dose left the stomach during the first 5 min.; subsequent emptying was slower, the next 40% of the dose requiring 15 min. to leave the stomach. An exponential function was representative of gastric emptying. The mean wt. of the stomachs plus contents in each group also approximated the amount of emptying. The front of the marker advanced through the 60% of the small intestine in the first 5 min. The end of the small intestine

MOTILITY

was not reached until 60 min., and the material never reached the cecum. The progression of the marker's front was thus correlated with gastric emptying. In the first 5 min., the greatest fraction of the dose that had left the stomach was found in the first 30% of the small intestine. After 15 min. the greatest part was in the 40-60% fraction of the intestine; after 30 and 60 min. it was seen in the 50-70% fraction of the intestine. It is concluded that this counting technic using the nonabsorbable indicator offers clear advantages over previously reported methods.

- 10897 ELECTRIC AND MOTOR EFFECTS OF AUTONOMIC DRUGS ON LONGITUDINAL ESOPHAGEAL SMOOTH MUSCLE. (E.) Christensen, J. (U. Alberta, Edmonton, Alberta, Canada) and E. E. Daniel. *Am. J. Physiol.* 211(2):387-394, 1966.

Tension and electrical activity in longitudinal muscle taken from the lowest 2 cm of cat esophagus was recorded at rest and in response to autonomic drugs. There were few or no contractions at rest, and electrical slow waves rarely occurred; during contractions, bursts of spike potentials accompanied slow waves. No qualitative differences were observed between spontaneous electrical events and those produced by drugs. Cholinergic drugs always caused contractions. Norepinephrine and epinephrine caused contractions which were opposed by tolazoline; isopropyl norepinephrine was inhibitory and opposed by propranolol. Excitation from norepinephrine was antagonized by atropine and hemicholinium, and anoxia decreased the response to norepinephrine. Sometimes the norepinephrine effect was reduced by removing tissue overlying the muscle. Norepinephrine sensitivity varied widely; responses to norepinephrine could be potentiated by physostigmine, but nicotine and hexamethonium did not affect the response to norepinephrine. The results suggest that adrenergic α -receptors are excitatory and β -receptors, inhibitory. The α -receptors are apparently located in postganglionic cholinergic nerves present, in part, in the esophageal plexus, whereas the β -receptors lie in the smooth muscle cells.

- 10898 EFFECTS OF OUABAIN AND 2,4-DINITROPHENOL ON Ca EXCHANGE IN TAENIA COLI. (E.) Pfaffman, M. (U. Mississippi Sch. Med., Jackson) and W. Holland. *Am. J. Physiol.* 211(2):400-402, 1966.

In guinea pig taenia coli, high conc. of potassium produced a tonic contraction which was abolished by 2,4-dinitrophenol (DNP; 10^{-4} M) and ouabain (2.5×10^{-6} M); experiments were conducted to ascertain the movement of calcium during the abolition of tonic contraction by these two agents. Tissue calcium and Ca^{45} uptake were decreased to control levels during abolition of tension by ouabain, but tissue calcium levels remained elevated with DNP. It is hypothesized that DNP blocks calcium levels, thereby depressing the calcium extrusion mechanism. Another hypothesis advanced is a metabolically dependent process that keeps the calcium entering the fiber in an exchangeable form. Ouabain may affect the potassium-induced calcium transport process at the fiber membrane; and inasmuch as ouabain inhibits many sodium-dependent transport processes, this calcium transport process may be coupled to an active sodium efflux.

- 10899 GLUCOCORTICOID-KININ ANTAGONISM IN THE RAT. (E.) Suddick, R. P. (Coll. Med., State U. Iowa, Iowa City). *Am. J. Physiol.* 211(3):844-850, 1966.

In adrenalectomized rats, inj. of crude rat submaxillary gland extract was immediately lethal unless the rats were immediately pretreated with corticosteroids such as cortisone acetate (5-15 mg/kg), hydrocortisone acetate (2-5 mg/kg), or deoxycorticosterone acetate (10-20 mg/kg). Bioassays on guinea pig ileum revealed that similar extracts contained considerable kinin-releasing enzyme activity; bradykinin, in doses similar to the assayed kinin-releasing potential of fatal doses of extract, was also lethal to adrenalectomized rats. Submaxillaryectomy was performed together with adrenalectomy to determine the effect on survival time (as compared with adrenalectomized controls) under different feeding conditions. When these rats were fed ad libitum throughout the experiment, survival times were longer in the controls. When both groups were deprived of food following

TILITY

rgery, survival times were significantly lower in the controls. The availability of food after surgery also had a marked effect on the survival time. It is suggested that corticosteroids may moderate the systemic effects of endogenous kinin(s). Extracts of parotid glands did not have this toxic effect. Submaxillary gland extracts were also lethal to hypophysectomized rats.

- 900 5-HYDROXYTRYPTAMINE RELEASE INTO DOG INTESTINAL VASCULATURE. (E.) Burks, T. F. (U. Iowa Coll. Med., Iowa City) and J. P. Long. Am. J. Physiol. 211(3):619-625, 1966.

en juxtaintestinal arteries of isolated intestinal segments of dogs were perfused with Krebs bicarbonate soln., the venous effluent soln. collected contained serotonin (5-hydroxytryptamine). Stimuli such as increasing intraluminal pressure, i.a. admin. of acetylcholine, and scratching the serosal surface of the isolated intestinal segment, markedly increased serotonin release. It is concluded that serotonin release may be involved in the physiological activity of the intestine, possibly including the peristaltic reflex; or it may supply additional serotonin for blood platelet transport.

- 901 TRANSMISSION OF REFLEXES ARISING ON BOTH SIDES OF THE GASTRODUODENAL JUNCTION. (E.) Daniel, E. E. (U. Alberta, Edmonton, Canada) and G. E. Wiebe. Am. J. Physiol. 211(3):634-642, 1966.

flex phenomena originating on both sides of the gastroduodenal junction were studied in anesthetized dogs; mechanical and electrical activity were recorded simultaneously from both sides. The reflex inhibitory effect of gastric distention on duodenal electrical and mechanical activity was blocked by reserpine (1 mg/kg i.v.) and guanethidine (15 µg/kg i.v.). Responses were temporarily restored by epinephrine (10-15 µg/kg i.v., or 10 µg i.a.) in reserpine-treated animals, but bilateral vagotomy and pyloric section did not abolish this response. Duodenal distention or marked contractions produced temporary slowing of the antral rhythm, with a corresponding reduction in the frequency of peristaltic contraction; bilateral vagotomy and chemical sympathectomy abolished this response. Pyloric section did not block this response in any of the animals.

- 902 PRESSURE RESPONSES OF CANINE ILEOCOLONIC JUNCTIONAL ZONE TO INTESTINAL DISTENTION. (E.) Kelley, M. L., Jr. (U. Rochester Sch. Med. Dentistry, N. Y.), E. A. Gordon and J. A. Deweese. Am. J. Physiol. 211(3):614-618, 1966.

Effects of transient intestinal distention on pressures in the ileocolonic junctional zone of conscious, fasted dogs were studied, using a fluid-filled, radiopaque recording balloon attached to a transducer, which was positioned fluoroscopically through the ileocecal junction in the structure which denoted the point of convergence of the small and large intestine. Stimulation was induced by inflating a small distending balloon in the colon (88 times) or ileum (131 times). Before stimulation, the mean junctional area pressure was 66 ± 2.2 cm H₂O above ambient. The most common junctional zone response to ileal stimulation by distention was a decline in pressure, interpreted as relaxation; this was frequently followed by an increase in pressure, indicating contraction. Contraction alone was more frequent with colonic distention, but relaxation was uncommon. No alteration in X-ray configuration of the junction occurred with either small or large intestine distention.

- 903 PATHOPHYSIOLOGY OF NON-PERISTALTIC TERTIARY CONTRACTIONS OF THE ESOPHAGUS. (Ger.) Lenz, H. (U. Bonn, Germany). Fortschr. Roentgenstr. 105(2):222-226, 1966.

tertiary contractions of the esophagus were analyzed in one patient by means of cineradiography. They were rhythmic contractions of circular muscles, probably of spastic nature, involving only the lower half of the thoracic esophagus. This phenomenon is believed to be identical with the "beaded appearance" or "curling" of the lower esophagus which has been demonstrated radiologically. Contraction of the circular fibers results in stretching of the longitudinal muscles in the segment affected by the spasm; this, in turn, leads to reflex relaxation of circular musculature, which is evident as pseudodiverticular dilatation of the esophagus.

MOTILITY

- 10904 EFFECTS OF STRYCHNINE, DERIVATIVES OF PHENYL ACETATE AND CATECHOLAMINES ON CONTRACTION AND ACETYL-CHOLINE OUTPUT FROM THE CHOLINERGIC NERVE ENDING OF GUINEA PIG ILEUM. (E.) Takagi, K. (U. Tokyo, Japan) and I. Takayanagi. Jap. J. Pharmacol. 16(2):211-216, 1966.

Strips of male guinea pig ileum, 5-6 cm long, suspended in aerated Tyrode's soln., maintained at 32°, were used for these experiments. In some tests the drug-induced contractions were studied directly; in others the effect of some agents upon the coaxial electrical-stimulated release of acetylcholine from the cholinergic nerve endings was investigated. The electrical stimuli were rectangular current pulses 1 msec in duration and of sufficient strength to produce a moderate response. The assay of acetylcholine released by the electrical stimulation was carried out on separate eserinated strips of ileum. The experiments on the diaphragm were done by stimulation of the phrenic nerve. Strychnine antagonized the responses directly induced by 5-hydroxytryptamine, picric acid, and nicotine, which accelerate the release of acetylcholine from cholinergic nerve endings, but had no effect upon the contractions produced by acetylcholine and phenylacetate. The acetylcholine output and contraction per shock caused by the coaxial stimulation at 0.1 cps was inhibited by strychnine (10⁻⁵ g/ml) and by morphine (10⁻⁶ g/ml) but not at a rate of 50 cps. Some phenyl compounds, (e.g., phenylacetate) stimulate contraction by causing release of acetylcholine from nerve endings; others do not. The inhibitory effect of catecholamines and reserpine seems to be by reduction of acetylcholine output of the cholinergic endings through a different action from that of morphine and strychnine. Morphine and strychnine in conc. up to 10⁻⁴ g/ml were without any effect upon contraction of the diaphragm elicited by stimulating the phrenic nerve.

- 10905 EFFECTS OF INTESTINAL MOVEMENT MODES ON THE PORTAL PRESSURE. (Jap.) Yagasaki, O. (U. Osaka Prefect.) and I. Yanagita. Nippon Yakurigaku Zasshi (Folia Pharmacol. Jap.) 62(4):152-157, 1966.

Blood pressure in the portal and mesenteric veins was recorded continuously in rabbits with isolated intestinal loops. Pulsatile changes synchronizing with intestinal contractions were noted, especially in the mesenteric veins. Peristalsis with strong contraction of the circular muscles resulted in an increase of 10 mm H₂O during contraction, followed by a decrease of 25 mm H₂O during relaxation, in the mesenteric vein; this was accompanied by a transient increase in venous output. Portal vein pressure changes were less intense. Other types of intestinal movement resulted in similar but less marked changes, sometimes less than 10 mm H₂O.

- 10906 RESPONSES OF LARGE AND SMALL INTESTINE OF THE RAT TO CESIUM, 5-HYDROXYTRYPTAMINE, OUABAIN AND ACETYL CHOLINE. (E.) Thevathasan, O. I. (U. Malaya, Kuala Lumpur) and J. W. Archdeacon. Med. J. Malaya 20(4):306-315, 1966.

Sections (1.5 to 2 in.) of large (proximal colon) or small intestine were removed from 24-36-hr. fasted male rats and placed in Palmer isolated organ bath. The tissue was fixed at one end and tied to a transducer by the other; the lumen of the intestine was exposed to the bath soln. (100 mM NaCl, 30 mM NaHCO₃, 1 mM CaCl₂, 2 mM KCl). The intestine was stretched by positioning the transducer. In some experiments KCl was omitted from the soln. CsCl (2 mM) increased rate of spontaneous contractions of both large and small intestinal sections usually associated with increased amplitude and frequency. The contractile changes were greater without KCl in the bath. Acetylcholine (0.6 x 10⁻⁷ M) attenuated the response to CsCl. Both intestinal preparations contracted to 5-hydroxytryptamine (5-HT; 1.7 x 10⁻⁶ M). The lack of K⁺ in the soln. had no effect. After exposure to 2 mM Cs⁺ in K⁺-free soln. which elicited contractions, 5-HT was reapplied and elicited little or no response. When acetylcholine (1.2 x 10⁻⁷ M) was applied the tissue in K soln. contracted, the tissue in non-K soln. did not. It is concluded that there was an antagonism between Cs⁺ and K⁺. The results suggest that CsCl does not act through acetylcholine or a cholinergic mechanism. Contractile response to 5-HT was not affected by lack of K⁺. Ouabain produced a more regulated rhythmic type of contractile pattern.

- 10907 RESPONSE TO INSULIN BY GUINEA-PIG TAENIA COLI. (E.) Grossman, J. L. (Univ. Coll., London; and K. L. Manchester. Nature (London) 211(5055):300-301, 1966.

MOTILITY

Guinea pig taenia coli muscle was selected for in vitro study of the effects of insulin because of its ease of dissection and less specialized function. Insulin was found to enhance uptake of glucose, increase retention of glycogen, and accumulation of aminoisobutyrate and the incorporation of C^{14} -labeled glycine into protein; however, these effects were not consistently seen. Estimates of extracellular fluid in taenia coli using sucrose and sorbitol were higher than those with inulin. Glucose space in taenia coli was estimated to be 24.9 compared to 27.5 in the presence of insulin, which was taken to indicate little intracellular accumulation. These data suggest that taenia coli responds to insulin, though the quantitative significance seems variable. It is possible that all tissues cannot be categorized as responsive or not to insulin, but that the response varies according to conditions, undetermined as yet, perhaps akin to the response of brain slices.

- 0908 EFFECTS OF INSULIN ON THE SMALL INTESTINE. STUDY ON THE RAT. (Fr.)
Aron, E., A. Rougureau and J. Thouvenot. C.R. Acad. Sci. (Paris) 262(24):
(Ser. D):2488, 1966.
Insulin had no significant effect on spontaneous or artificially-induced contractile activity of rat intestine in vitro, when added to the incubation medium or inj. into the intestinal wall. However, when introduced into the intestinal lumen, it increased tonic resistance to both chemical and electrical contractile stimulation markedly, to such an extent that a section of jejunum taken 40-44 cm from the pylorus reacted like a section of duodenum, even at temperatures ranging from 18-28°C. There appeared to be no relationship between the amplitude of the tonic resistance and the dose of insulin, up to 10^{-9} I.U. The effect was suppressed readily by trace doses of trypsin and could not be replicated by any conc. of ovalbumin, peptones, ptyalozyme, glutathione or zinc chloride.

HEPATIC METABOLISM

- 10917 POSSIBLE ROLE OF P-450 IN THE OXIDATION OF DRUGS IN LIVER MICROSOMES. (E.) Kato, R. (Nat. Inst. Hygiene Sci., Tokyo). *J. Biochem. (Tokyo)* 59(6):574-583, 1966.

In rats, admin. of phenobarbital (70 mg/kg) increased the amount of microsomal cytochrome binding carbon monoxide (P-450) in the liver microsomes (max. after 24-36 hr.); this increase almost paralleled drug oxidation activity. This increase by phenobarbital was greatly enhanced in fasted animals. In contrast, a sucrose diet caused a decrease in the amount of P-450. Rats treated with methylcholanthrene (40 mg/kg) also showed an induction of P-450 synthesis along with drug oxidizing activity. Little or no P-450 was found in the liver of the rat fetus or newborn, but the amount increased progressively until 30 days of age, then gradually decreased. Drug oxidation activity followed a similar pattern. In the rat, the highest conc. of P-450 was seen in the liver; the conc. was low in the kidney and lung and negligible in the brain, muscle, and heart. Drug oxidation varied in the same manner. In a survey of various species, P-450 conc. was highest in the mouse liver and lowest in the cat liver. Again, drug oxidation activity varied similarly. Increased conc. of atmospheric carbon monoxide inhibited drug oxidation activity in rat livers and produced a decrease in the conc. of free P-450. A possible mechanism for the oxidation of drugs is proposed from these results.

- 10918 INHIBITION OF DNA SYNTHESIS IN ASCITES HEPATOMA CELLS BY NORMAL LIVER EXTRACT. (E.) Otsuka, H. (Fac. Sci., U. Tokyo, Japan) and H. Terayama. *Biochim. Biophys. Acta* 123(2):274-285, 1966.

Marked inhibition of DNA synthesis was observed in AH-414 ascites hepatoma cells after 2-6 hr. of incubation *in vitro* with various conc. of cell sap from normal rat liver. In contrast, RNA synthesis was hardly affected. The degree of inhibition caused by the cell sap depended on its conc. and was removed with washing. Cell sap obtained from rat brain; spleen, kidney or regenerating liver displayed this same inhibitory property, as did nuclear sap obtained from a normal rat liver. However, cell extract or cell sap from ascites hepatoma cells or from 3'-methyl-4-dimethylaminoazobenzene-induced primary hepatomas caused no *in vitro* inhibition of DNA synthesis. When the cell sap from normal liver was adjusted to pH 4.5 and centrifuged for 10 min., the substance inhibiting DNA synthesis *in vitro* was found in the supernatant. This active substance was thermolabile and displayed protein-like features, having an isoelectric point near pH 7.0. The possible role of this active substance as a control mechanism of cellular growth is discussed.

- 10919 REGULATION OF SYNTHESIS AND TURNOVER OF FERRITIN IN RAT LIVER. (E.) Drysdale, J. W. (Massachusetts Inst. Techn., Cambridge, Mass.) and H. N. Munro. *J. Biol. Chem.* 241(15):3630-3637, 1966.

Admin. of iron (400 μ g/100 g, i.p.) to fasted rats, followed by 2 hr. pulse doses of leucine- C^{14} , induced an extensive increase in labeling of ferritin protein, but had no effect on labeling of mixed liver protein. The increase in labeling of ferritin protein peaked at 5 hr. and subsided by 12 hr., at which time the amount of ferritin protein and ferritin iron in the liver had peaked at about double the original level. This ferritin response induced by iron was dose-dependent and insensitive to actinomycin D. Repeated inj. of iron over a 72-hr. period following leucine- C^{14} admin. increased the iron/protein ratio of ferritin and retarded the loss of radioactivity. Separation of ferritin according to differing iron content showed that the first fraction to become labeled after inj. of leucine- C^{14} was low in iron, with a subsequent progressive transfer of the label to ferritin fractions richer in iron. Repeated iron inj. resulted in retention of a larger portion of the initial radioactivity of the iron-poor fraction as the iron-rich ferritin. It is proposed that iron can cause an apparent induction of ferritin metabolism by stabilizing a precursor which would otherwise be degraded and by stabilizing iron-poor ferritin by increasing its iron content, thereby retarding its degradation.

HEPATIC METABOLISM

- 10920 EFFECT OF IRRADIATION ON DNA-SYNTHESIS IN THE REGENERATING LIVERS OF RATS. (E.) Lehnert, S. M. (U. Rochester Sch. Med. Dent., N. Y.) and S. Okada. *Int. J. Radiat. Biol.* 10(6):601-608, 1966.

The thymidine kinase and DNA polymerase activities of the regenerating liver in rats were depressed by exposure to 800 r of X-rays following partial hepatectomy. A comparable enzymatic depression was seen in partially hepatectomized rats inj. i.p. with either 8-azaguanine (100 mg), actinomycin D (1 mg), or ethionine (300 mg) total doses. When either 300 mg (total) of thymidine or 1500 mg (total) of deoxy-cytidylic acid were given at the time of irradiation, the enzymatic depression still occurred. In nonirradiated regenerating liver, the priming ability of nuclei showed 2 peaks of activity, one 6 hr. and the second at 24 hr. after hepatectomy. In contrast, the priming ability of nuclei of regenerating liver irradiated 24 hr. after hepatectomy remained at a low level at all times. In addition, the rate of incorporation of thymidine in the nonirradiated regenerating liver *in vivo* exceeded that of the irradiated ones at all times. Comparison between the *in vivo* and *in vitro* studies showed that in nonirradiated regenerating liver, max. nuclear priming ability did not coincide with the *in vivo* peaks of thymidine incorporation, whereas the degree of depression of enzyme activity paralleled the actual depression of DNA synthesis in irradiated animals, indicating that the latter is the major factor regulating DNA synthesis.

- 10921 STUDY OF THE HEPATIC INCORPORATION OF SHORT- AND INTERMEDIATE-CHAIN FATTY ACIDS IN THE DOG. (Fr.) Bézard, J. (Fac. Sci., Dijon, France), G. Clément, J. Klepping and S. Briet. *Arch. Sci. Physiol. (Paris)* 20(2): 169-180, 1966.

Fasting male dogs were fed a single meal of chopped meat containing approx. 10% caproic acid by total vol.; catheters were inserted 30 min. later under anesthesia and blood samples were taken from the portal vein and 1 of the suprahepatic veins 100-220 min. after feeding. In control animals receiving only meat, no significant quantities of caproic, caprylic, capric, lauric or myristic acid could be demonstrated at any time interval; in treated dogs, they made up 5-15% of the total fatty acid content of serum lipids found in the portal vein 100 min. after feeding, the remainder consisting of saturated and unsaturated long-chain fatty acids. Caproic and caprylic acid were found only in the first blood sample, and only in the form of free acids; capric, lauric and myristic acids were present in all blood samples, chiefly in the form of triglycerides; they reached their highest conc. between 50-180 min., presumably due to transport by the lymphatic system. In the first sample, the contents of total fatty acid present in the free acid form varied inversely according to the length of the chain (myristic = 22%, lauric = 37%, capric = 72%, caprylic and caproic = 100%). Caproic and caprylic acid could not be demonstrated at any time in blood from the suprahepatic vein, confirming hepatic incorporation of the total amounts present in the portal circulation. The extent to which free capric, lauric, and myristic acids were incorporated into the liver varied inversely according to the length of the chain, although the corresponding triglycerides were incorporated in approx. equal quantities, irrespective of the length of the chain. It is concluded that hepatic incorporation of short- and intermediate-chain fatty acids occurring in the form of triglycerides involves a different mechanism of action from that involved in incorporation of the free acids.

- 10922 METABOLISM OF TRANS ACIDS IN THE RAT: INFLUENCE OF THE GEOMETRIC ISOMERS OF LINOLEIC ACID ON THE STRUCTURE OF LIVER TRIGLYCERIDES AND LECITHINS. (E.) Privett, O. S. (U. Minnesota, Austin), L. J. Nutter and F. S. Lightly. *J. Nutr.* 89(3):257-264, 1966.

The structure of liver lecithins and triglycerides was studied in male Sprague-Dawley rats with dietetically-induced fatty acid deficiencies after 18-20 days of feeding with the *cis*-9/*cis*-12, *cis*-9/*trans*-12, or *trans*-9/*trans*-12 isomers of methyl linoleate alone, in various combinations, or as various combinations with linolenate. After enzymatic hydrolysis of the lecithins and triglycerides, the *cis*/*cis* and *cis*-1/*trans*-12 isomers of linoleic acid were esterified in the second position and the *trans*/*trans* isomer was esterified in the primary position. The saturated fatty acids were esterified predominantly in the primary positions, while the *trans*/*trans*

HEPATIC METABOLISM

isomer of linoleic acid was esterified predominantly in the primary position in all molecular species except those containing saturated fatty acids. The cis/cis isomer was esterified in the β -position except when associated with arachidonic acid, which itself was always esterified in the β -position.

- 0923 LIVER TRANSPLANTATION EFFECTS ON CANINE PLASMA LIPIDS. (E.) Worth, W. S. (VA Hosp., U. Colorado Med. Ctr., Denver), N. L. Miller and P. D. Taylor. *Nature (London)* 211(5044):78-79, 1966.

Serum lipid levels were studied in 3 dogs with transient liver function disturbance after implantation of orthotopic hepatic homografts under cover of azathioprine (Imuran), methionine and antibiotics. At the time of report, 1 dog had died after 100 days with jaundice, and the others were alive with good liver function after 285 and 295 days. Total serum cholesterol levels were reduced by approx. 50% during the first 10 postoperative days, but returned to preoperative values 30-40 days postoperatively. Spontaneous reversal of a similar decline of serum phospholipids also began after day 10 after surgery and was complete by day 30. Serum triglyceride and nonesterified fatty acid levels did not fluctuate significantly. Thin-layer chromatographic studies of lecithins, sphingomyelin, lysolecithin and phosphatidylethanolamine indicated uniform changes in the serum content of all 4 phosphatide fractions at 5, 10, 20 and 30 days after surgery, appearing to confirm that the indicated changes of total serum phospholipid content were not attributable to any one particular phosphatide. The immunosuppressive agent azathioprine had no significant effect on serum lipid profiles. It is concluded that the changes observed may indicate the presence of a physiological host mechanism of defense against the homograft per se or against operational shock.

- 10924 STUDY OF POSSIBILITIES OF HEPATIC SURVIVAL IN LIEU OF PURIFICATION AND TRANSPLANTATION. (Fr.) Leger, L. (Cochin Hosp., Paris), Y. Chapuis, J. Y. Neveux, J. P. Lenriot, J. C. Patel, L. Langrand, G. Woell and P. Frenoy. *Mem. Acad. Chir. (Paris)* 92(18-19):497-504, 1966.

Preliminary orthotopic and heterotopic transplantations of dog livers were made to determine the best way to remove the organ with minimal damage to the vascularization. Experiments with various doses of Imuran and Endoxan were conducted to determine best amounts to prevent rejection. Hypothermia (-70° or $+25^{\circ}$ C) was used to prevent damage of the hepatic cells; a return to normal circulation occurred in 10 dogs undergoing subsequent hepatic perfusion. A possible alternate circuit for perfusion was studied by cannulation of the femoral artery and sending the blood to a reservoir 25-35 cm below the liver. The blood drained into the portal vein and was shuttled into the femoral vein by a pump and purified by cross-transfusion into living animals with normal arterial pressure. Before removal of the liver the peritoneal cavity of anesthetized dogs was cooled. A few min. before hepatectomy the liver was bled and washed with Ringer-Locke's soln. at 4° C. Control was determined by watching the arterial tension, portal inj. tension, bilirubin levels, O_2 - CO_2 exchange, transaminases in the blood, temperature and pH. Under these conditions, 10 of 13 perfusions (3-8 hr.) were successful. Delivery of blood across the liver was at a rate of 0.50-0.80 ml/g/min. When a sudden fall occurred the change was irreversible and deleterious. Bile production during the operation was about 0.56 ml/100 g of liver and was greater during the second 60 min.; blood levels were about 26 mg/100 ml; oxygen consumption was stable at 0.026-0.036 ml/min./g of liver. Infrared lamps were used to maintain temperature and prevent desiccation. The pH was variable, often above 7.35 and sometimes as low as 7.25. Return of circulation occurred in the first 10 min., but varied with the area of the liver. Return to normal vol. occurred in the first few min. Histologic examination of dogs with hepatic congestion showed sinusoidal congestion, dilation of the portal venules and degranulation of the cytoplasm.

- 0925 PERFUSION OF THE ISOLATED LIVER N SITU. (It.) Battezzati, M., A. Cattaneo and . Donini. *Rev. nt. Hepat.* 5(8):439-446 1966.

Attempts to improve surgical means of perfusing dog livers consisted of a bypass pump system set up between the inferior vena cava and the external jugular vein, to direct the perfusion circulation between the inferior vena cava and the portal vein

ing across a branch of the splenic vein. A bubbling aspiration device was attached to an oxygenating system supplying 30 mm Hg pressure and 200-300 ml blood/min. At brief intervals, specimens from the hepatic vein were taken to determine hemoglobinemia, free and conjugated bilirubinemia, sulfobromophthalein retention and aspartic-pyruvic transaminase levels; these varied only slightly during the operation. Difficulties in the manipulation of the inferior vena cava and occluded portal vein were found, but gradual occlusion of the portal vein was tolerated better than rapid occlusion which upset the circulating homeostasis. The liver perfusion was maintained in equilibrium by the hepatic and portal arteries. Resistance seemed to diminish as the pressure increased, but resistance was the greatest problem of liver perfusion. This technic appears to be adequate in successful liver perfusion.

926 THE QUESTION OF LIVER-SPECIFIC ANTIGENS IN MAN. (Ger.) Licht, W. (U. Surg. Clin., Homburg/Saar, Germany). *Klin. Wschr.* 44(14):833-837, 1966. Immune diffusion and immunoelectrophoretic studies performed on saline extracts of human liver, lung, kidney, spleen, and uterus in reactions with plasma and/or with rabbit anti-human liver immune serum, showed a number of plasma proteins and several organ-specific antigens common to all organ extracts tested. Absorption experiments, however, showed 2 liver proteins not found in other extracts and therefore considered specific for the liver. Two of the components showing only liver specificity were common to liver, lung, and spleen, but were not present in kidney extracts, indicating that the antigenic composition of kidney tissue is different from that of the liver, even with respect to cross-reacting (unspecific) antigens.

927 MECHANISM OF BIOLOGICAL ACTION OF DICHLOROACETIC ACID. (Rus.) Novikova, M. A. (Inst. Chem. Native Compounds, Acad. Sci. USSR, Moscow), G. A. Popikova and A. V. Chestukhin. *Vop. Med. Khim.* 12(3):240-247, 1966. Marked changes in total hepatic lipids (marked increase to max. at 12 hr. with normalization by 96 hr.) and sugar and glycogen content (steady, significant decrease) in regenerating rat liver were intensified when dichloroacetic acid (1 g/kg i.p.) was admin. 1 hr. after hepatectomy. The changes in DNA, RNA, and protein content were about the same in both groups. Treatment with dichloroacetic acid or dichloroacetyethanolamine (2 g/kg i.p.) markedly stimulated liver tryptophan pyrrolase activity, whereas adrenalectomy caused a depression of this enzyme. Tryptophan pyrrolase activity was decreased markedly by induction with DL-tryptophan (10 mg/kg i.p.); N-dichloroacetyethanolamine stimulated this induction in adrenalectomized rats. The initial velocity of enzymatic reactions in the livers of normal and (to a lesser extent) adrenalectomized rats was increased by treatment with DL-tryptophan together with dichloroacetic acid. Dichloroacetic acid alone had no effect on hepatic tryptophan pyrrolase activity. A marked increase in tryptophan pyrrolase activity *in vitro* was seen after addition of hematin (0.1 mg/ml of 0.005% soln.) to liver preparations from rats treated with DL-tryptophan or hydrocortisone (5 mg/kg i.p.) 3 hr. before sacrifice. Treatment with dichloroacetic acid together with inductor stimulated tryptophan pyrrolase activity in the presence or absence of the cofactor. In normal rats, treatment with dichloroacetic acid together with DL-tryptophan or with tryptophan alone stimulated tryptophan pyrrolase activity. After admin. of dichloroacetic acid alone, enzyme activity was still low, and saturation with the coenzyme was seen. Dichloroacetic acid also stimulated tryptophan pyrrolase induction in adrenalectomized rats, whereas 3 hr. after hydrocortisone admin. only the apoenzyme was seen. Tryptophan induced the apoenzyme, while dichloroacetic acid stimulated induction by hydrocortisone.

928 PERINATAL CHANGES IN THE FAT CONTENT OF RAT LIVER. (E.) Morikawa, K. (U. Osaka, Japan) and M. Eguchi. *Endocr. Jap.* 3(2):189-192, 1966. Liver fat content of 20-, 21-, 22-, and 24-day-old rat fetuses and of 1-, 2-, and 3-day-old newborn rats was determined after extraction of total lipid with chloroform:methanol. The 24-day-old fetuses were maintained in prolonged pregnancy treatment of the mother with progesterone (2.5 mg on days 21, 22, and 23 of pregnancy). Although the liver wt. increased as the rats neared term (201-328 mg)

HEPATIC METABOLISM

the liver fat content tended to decrease (2.50 to 2.02 mg/mg wet wt.). In rats maintained in utero by progesterone, the liver fat content increased to 2.73 mg/100 mg liver wet wt. At birth the liver wt. decreased to 234 mg (compared to 328 mg at 22 days prenatal), whereas the liver fat content increased from 2.02 mg wet wt. liver to 5.76 mg. In Caesarean-delivered premature rats (22 days), the fat content increased by 6 hr. after delivery from 1.90-2.33 mg/100 mg wet wt. liver. It is suggested that the neonatal liver loses certain enzymes involved in lipid metabolism and may also have an altered potential to respond to lipid-mobilizing hormones.

- 10929 METHOD OF PERFUSION OF ISOLATED RAT LIVERS. (Ger.) Meiers, H. G. (U. Düsseldorf, Germany), J. Flammann, G. Albaum and W. Staib. *Biochem. Zschr.* 344(5):514-523, 1966.

Diluted rat blood and semisynthetic bovine blood were compared as perfusion media for isolated rat livers. Hemolysis and an increase in serum proteins (especially β -globulin) were seen with both media. Because hematocrit levels in rat blood are higher, hemolytic activity was greater in the rat blood medium (av. hemoglobin up to 1.8 g%, compared to 0.63 g% with bovine medium), as were bile secretion (over 200 and under 150 μ l/g liver, resp.) and urea production (urea nitrogen was 1.3 and 0.8 mg/g liver, resp.) after 6 hr. of perfusion. Blood glucose values decreased rapidly in the rat blood medium; cumulative glucose balance in the perfused livers fell up to 3.5 mg/g liver (corrected for erythrocyte glycolytic activity) in the first 30 min. and remained about the same for the next 5 hr. In the bovine medium, glucose depletion was gradual and steady, reaching this level after 6 hr. Continuous enzyme production was seen in the perfused livers; enzyme activity rose markedly if the perfusion rate fell below the critical level of 0.6 ml/g/min. It is concluded that the semisynthetic bovine blood medium is preferable for perfusion studies.

- 10930 BIOTIN DEFICIENCY AND RELATIVE INCORPORATION OF (^{14} C) FATTY ACIDS INTO CHICK LIVER PHOSPHOLIPIDS AND TRIGLYCERIDES. (E.) Donaldson, W. E. (North Carolina State U., Raleigh). *Biochem. Biophys. Res. Commun.* 24(3):443-446, 1966.

Two groups of chicks were fed biotin-deficient diets for 3 wk. after hatching, then received single doses of C^{14} -labeled palmitic or stearic acid (p.o.) 2 hr. before sacrifice. In chicks fed palmitic acid, the mean ratio of hepatic phospholipid to hepatic triglyceride incorporation was 0.69 (compared to 0.40 in normal controls); after feeding stearic acid it was 1.38 (controls 0.47). Both differences were statistically significant. It is concluded that the absence of dietary fatty acids in the biotin-deficient chicks reduced the total pool of fatty acids and also impaired the capacity for de novo synthesis. A similar phenomenon occurs with reduced caloric intake or starvation; in both cases, incorporation of fatty acids into hepatic triglycerides was reduced relative to their incorporation into hepatic phospholipids.

- 10931 EXPERIMENTAL STUDIES ON LIVER COENZYME A. I. SEASONAL VARIATIONS OF LIVER COENZYME A IN PANTOTHENIC ACID DEFICIENT RATS. (E.) Kanematsu, Y. (Kyoto U. Fac. Med., Japan). *Naika Hokan (Jap. Arch. Intern. Med.)* 13(3):127-132, 1966.

The liver coenzyme A (CoA) conc. (in U/g of fresh tissue) of both adult and young male Wistar rats was approx. 30 U higher than that of old rats, whereas the pantothenic acid (PA) conc. did not vary significantly in any of the groups, even though the contents varied greatly from animal to animal. In young rats fed a PA-deficient diet (containing less than 80 μ g/100 g dry wt.), the wt. gain stopped after about 5 wk. of treatment, followed by a wt. loss after 7 wk., resumption of wt. gain by 10., and another wt. loss at 24 wk. Both periods of wt. loss occurred during warm weather. In both PA-deficient and control rats, the liver CoA increased gradually towards winter and then decreased, although the levels were lower in the PA-deficient rats. In the control rats, the January values were 34% higher than those August. The rate of acetylation of p-aminobenzoic acid was significantly decreased in winter in both control and PA-deficient rats. These seasonal studies show that rats fed on PA-deficient diet were more apt to become PA-deficient in warm or hot weather than in cold weather.

- 932 STUDIES ON CARBOHYDRATE METABOLISM IN LIVER. III. STUDIES ON CARBOHYDRATE METABOLISM IN REGENERATING RAT LIVER FOLLOWING PARTIAL HEPATECTOMY. (E.) Sakamoto, K. (Kyoto U. Fac. Med., Japan). Naika Hokan (Jap. Arch. Intern. Med.) 13(3):139-150, 1966.

The activities of glucose-6-phosphate dehydrogenase (G-6-PD), glucose-6-phosphatase (G-6-Pase) and phosphohexose isomerase (PHI) were determined in regenerating rat livers 12 hr.-14 days following a partial hepatectomy. The G-6-PD activity (expressed on a wet wt. basis) increased at 12 hr., peaked at 2 days, then declined to normal by day 14; the total available G-6-PD activity showed a significant increase between days 2 and 7. This early marked increase of G-6-PD activity preceded the restoration of the acid-soluble nucleotide and nucleic acid contents. In addition, the decrease to normal of G-6-PD activity occurred upon the cessation of synthesis of nucleotides and nucleic acids, which suggests that the initiation of nucleic acids and nucleotide synthesis may be associated with an elevation of G-6-PD activity. The G-6-Pase activity was not significantly different in the regenerating liver and the PHI activity only differed slightly from the sham-operated controls. In the regenerating liver, the rate of incorporation of radioactivity from glucose-6- C^{14} into the nucleic acids and acid-soluble fraction did not vary significantly from that of glucose-1- C^{14} , indicating that the pentose moiety may be synthesized by a transaldolase-transketolase reaction rather than by a direct oxidative decarboxylation pathway.

- 933 THE HEPATIC REMOVAL OF ^{14}C -HISTAMINE FROM THE BLOOD IN MAN. (E.) Lindell, S. E. (Sahlgrenska Hosp., Gothenburg, Sweden) and H. Westling. Scand. J. Clin. Invest. 18(13):268-272, 1966.

The extraction of infused histamine- C^{14} from splanchnic region blood of 3 healthy subjects demonstrated that the splanchnic area has a considerable capacity for removing histamine from the blood. The histamine- C^{14} was infused slowly (i.v. at a dosage of approx. 0.1 μ g base/kg/min.) and in 20 min. blood samples were taken from the splanchnic artery and the hepatic vein. At that time, the conc. of label was much lower in the hepatic venous blood than in the arterial blood. The extraction of histamine- C^{14} from whole blood during passage of the splanchnic circulation varied between 70-92%; the amount of histamine- C^{14} taken up in the splanchnic area/min. was 21-24% of the dosage/min. A much smaller amount of C^{14} -labeled methylhistamine was also isolated from the blood of all 3 subjects. In 1 subject, an increase in methylimidazoleacetic acid and imidazoleacetic acid conc. was seen after passage through the splanchnic circulation, whereas these conc. decreased in the other 2 subjects. Evidence from previous papers indicated that this removal of histamine during the passage of the splanchnic circulation takes place in the liver and is depressed only in the presence of severely impaired liver function.

- 934 IMMUNOELECTROPHORETIC STUDIES ON PROTEINS IN BILE AND GALLSTONE. (E.) Katsuki, T. (Kagoshima U., Japan) and A. Tsuchimochi. Acta Med. Univ. Kagoshimaensis 8(1):73-78, 1966.

Immunoelectrophoretic technics allowed the identification of 20 or more immunoprecipitin arcs between both human serum and plasma and rabbit anti-human serum. Tests made on human hepatic bile samples showed more than 15 protein fractions sharing antigenic determinants with human serum proteins. Many of these protein fractions were found in the α - and β -globulin areas. Rabbit anti-human fibrinogen immune serum formed a single precipitin arc of fibrinogen with both human plasma and human hepatic bile; this common antigenic determinant was not seen with human serum. The presence of human fibrinogen in hepatic bile was further confirmed by immunoelectrophoretic comparison with commercially prepared anti-human fibrinogen immune serum. Gallstone proteins extracted with barbital buffer contained albumin and possibly a prealbumin which shared antigenic determinants with human serum proteins. No other precipitin arc was observed with these gallstone extracts; other proteins common to human serum could be present in gallstones but not be extracted by another method.

- 10935 ENHANCED FORMATION OF RAPIDLY LABELED BILIRUBIN BY PHENOBARBITAL: HEPATIC MICROSOMAL CYTOCHROMES AS A POSSIBLE SOURCE. (E.) Schmid, R. (U. Chicago, Ill.), H. S. Marver and L. Hammaker. Biochem. Biophys. Res. Commun. 24(3):319-328, 1966.

In phenobarbital-treated (80 mg/kg/day for 5 days before label admin., then for 48 hr. more during bile collection) Sprague-Dawley rats, an increase in microsomal cytochromes (particularly Cytochrome P-450) was seen which paralleled an enhanced incorporation of C^{14} -glycine into bile pigment and an increase in bile pigment formation from nonhemoglobin sources. These data suggest that the cytochromes in the hepatic microsomal membrane are a major source of the "early-labeled" pigment (ELP) fraction of bile (which comprises 15% of all bile pigment formed). Fraction isotope incorporation into bilirubin was increased 6-fold during the initial collection periods and approx. 3-fold during the remainder of the experiment in the phenobarbital-treated rats. The av. ELP in the control rats was 8.8 μ g bilirubin/hr., whereas the av. for the treated rats was 54 μ g/hr. Microsomal cytochrome and, to a lesser extent, tryptophan pyrrolase were the only heme proteins which increased with phenobarbital treatment.

- 10936 THE EFFECT OF BUTYLATED HYDROXYTOLUENE, BUTYLATED HYDROXYANISOLE AND OCTYL GALLATE UPON LIVER WEIGHT AND BIPHENYL 4-HYDROXYLASE ACTIVITY IN THE RAT. (E.) Creaven, P. J. (St. Mary's Hosp. Med. Sch., London), W. H. Davies and R. T. Williams. J. Pharm. Pharmacol. 18(8):485-489, 1966.

In rats fed butylated hydroxytoluene (0.01-0.5%/day for 12 days), body wt. was unchanged but liver wt. was increased. Microsomal biphenyl 4-hydroxylase activity was also increased at all doses except the lowest. Feeding of the highest dose of this agent for 1 day resulted in an increase in liver wt. which was observed 2 day later and persisted for 3 days, followed by a return to normal liver wt. Feeding of butylated hydroxyanisole (0.1-0.5% of diet) did not affect liver wt. at any dosage; the highest dosage caused some increase in enzyme activity. Octyl gallate (0.5% in diet for 9 days) was inactive in both respects. Feeding a high-fat diet for 12 days increased enzyme activity but had no effect on liver wt.

- 10937 INFLUENCE OF CORTISONE ON WATER METABOLISM IN DOGS UNDER NORMAL CONDITIONS AND IN EXPERIMENTAL LIVER PATHOLOGY (Rus.) Sulakvelidze, T. S. (North Ossetian Inst. Med., Ordzhonikidze USSR). Fiziol. Zhur. SSSR. Secenov 52(5):588-594, 1966.

In healthy dogs with gastric and bladder fistulas, treatment with cortisone (1.25-5.0 mg/kg i.v. every 10 days) caused a slight diuresis at the expense of some decrease in the level of reverse water absorption in the renal canaliculi, but the glomerular filtration rate and renal plasma circulation remained unchanged. In dogs with gastric and bladder fistula associated with liver damage caused by ingestion of the common bile ducts (2) straight or reversed Eck-Pavlov fistulas (4) or carbon tetrachloride treatment for 5 mo. (1), treatment with cortisone during the period of marked inhibition of water diuresis reversed this antidiuretic effect and decreased the level of reverse water absorption in the renal canaliculi, while causing an increase in the glomerular filtration rate and renal plasma circulation. These changes were unstable. The diuretic effect of cortisone in dogs with liver damage was accompanied by a decrease in the antidiuretic activity of the blood. It is concluded that the inactivation of cortisone by the liver decreases in the presence of liver damage.

- 10938 THE EFFECT OF CORTISONE ON URINARY EXCRETION IN DOGS WITH VARIOUS FUNCTIONAL CONDITIONS OF THE LIVER. (Rus.) Sulakvelidze, T. S. (Severo-Osetian Inst. Med., Ordzhonikidze USSR). Probl. Endokr. Gormonozh. 12(4):88-92, 1966.

A somewhat more extensive report of the studies described in No. 10937.

- 10939 EFFECTS OF PROTEIN DEFICIENCY ON HEPATIC PARENCHYMAL CELLS: ELECTRON MICROSCOPIC OBSERVATIONS. (L.) Ericsson, G. L. G. (Karolinska Inst., Stockholm, Sweden). S. Örnberg and L. Hult. Acta Chir. Scand. 135: 106-110, 1966.

HEPATIC METABOLISM

four dogs maintained on a protein-free diet for 28 days, and 3 dogs (controls) given a normal, protein-rich ration, were sacrificed and the histologic structure of the liver was examined. The hydropic degeneration resulting from a protein-free diet was due to pronounced accumulation of glycogen in the cytoplasm; this was associated with spatial rearrangement of cytoplasmic organelles to the peripheral and perinuclear portions of the cytoplasm. Mitochondria were decreased in number and showed frequent abnormalities in shape, size, and structure of the matrix and cristae. The endoplasmic reticulum also showed structural abnormalities. Nuclear alterations included enlargement of nucleoli (up to 3.5μ in diameter), an increased number of nucleolar ribosomes, and abnormal distribution of chromatin.

- 0940 THE FATTY ACIDS OF HUMAN THORACIC DUCT LYMPH LIPIDS. ALTERATIONS PRODUCED FOLLOWING THE INGESTION OF DIFFERENT DIETARY FATS. (E.) Werner, B. (Karolinska Inst., Stockholm, Sweden). Acta Chir. Scand. 132(1/2):77-92, 1966.

The fatty acid composition of cholesterol esters, triglycerides and phospholipids of human thoracic duct lymph was analyzed by gas-liquid chromatography in 9 fasting patients and in 4 patients after feeding different vegetable oils (coconut, olive, corn, linseed, or rapeseed oil) in 4 patients. Fatty acid composition of corresponding lipid classes in fasting serum from the same patients was also studied, as well as the fatty acid composition of different lipid classes of the liver in 5 other patients. The most pronounced difference was the higher composition of linoleic acid in serum cholesterol esters as compared with those of lymph. Lymph cholesterol ester fatty acid composition was influenced to a different degree by the various vegetable oils, depending upon their fatty acid composition. Liver cholesterol esters contained about 70% unsaturated fatty acids; about 29% was linoleic acid, which was considerably less than in serum cholesterol esters. In thoracic duct lymph, triglycerides were influenced to the greatest extent by the test meal. Fatty acid composition of triglycerides was almost identical with that of the test meal, 3-8 hr. after ingestion of the various vegetable oils. Phospholipid fatty acid and free fatty acids were influenced very little by the dietary fat in serum, lymph, or liver.

- 0941 INTRACELLULAR DISTRIBUTION OF VITAMIN D IN RAT LIVER. (E.) Nair, P. P. (Sinai Hosp., Baltimore, Md.) and C. Bucana. Biochim. Biophys. Acta 124(2):254-259, 1966.

The distribution of ergocalciferol and cholecalciferol (vitamin D_2 and D_3 , resp.) in the various intracellular compartments of the liver tissue was studied in rats with respect to the route of admin. and the dosage used (200 μ g or 2000 μ g i.v., i.o. or i.p.); the livers were examined in an in vitro perfusion study 15 min. later. Liver uptake was 3.9% of dose after i.v. or i.p. admin. of 2000 μ g. In the isolated liver perfusion system using 2 dosages of ergocalciferol (200 or 2000 μ g i.v.), equilibrium was generally established within 1 hr., then the liver was fractionated by differential centrifugation and extraction of the subcellular fractions, which were analyzed by biphasic gas chromatography. At the low dosage, intracellular distribution was: supernatant 76.2%, microsomal fraction 5.5%, mitochondrial fraction 8.4%, and nuclear fraction 9.9%. At the high dosage intracellular distribution was 31.5%, 8.9%, 8.4%, and 38.1%, resp. Final conc. of the vitamin in the liver at the low dose was 18.4 μ g/g liver (wet wt.); final conc. at the high dose was 28.2 μ g/g liver (wet wt.). Irrespective of the route of admin., the vitamin was predominant in the cytoplasmic compartment. There was no discoverable correlation between protein conc. and vitamin conc. No significant difference was apparent between the metabolism of the 2 forms of vitamin.

- 0942 METABOLISM OF CHOLESTEROL IN RETICULOENDOTHELIAL HYPERFUNCTIONAL RATS MAINTAINED ON NORMAL OR HIGH CHOLESTEROL DIETS. (E.) G. Luzio, M. P. (U. Tennessee, Memphis) and G. J. Riggi. Am. J. Reticuloendothel. Dis. 3(2):135-148, 1966.

Rats maintained on a high cholesterol diet stimulation of reticuloendothelial (R.E.) activity by glucan admin. inhibited the accumulation of plasma and liver ester cholesterol. Vascular clearance and tissue distribution (liver, lung and spleen)

HEPATIC METABOLISM

of 4- C^{14} -cholesterol-labeled chylomicrons 10 min. after their i.v. inj. were not significantly altered in control and RE-hyperfunctional rats maintained on a normal or a high-cholesterol diet. In comparison to rats maintained on a normal diet, control and RE-hyperfunctional cholesterol-fed rats displayed significant retention of radioactive cholesterol in the liver, but not in the spleen or lungs, 24 hr. after i.v. admin. of cholesterol-labeled chyle. The p.o. admin. of 4- C^{14} -cholesterol to normal and RE-hyperfunctional rats on high cholesterol intake caused a significant decrease of hepatic radioactivity in RE-stimulated rats, which was not associated with any alteration in spleen and lung or plasma radioactivity. Cumulative fecal excretion of radioactivity over a 6-day period was not different in the stimulated group, indicating that enhanced biliary excretion of cholesterol or its metabolites was not a factor in the observed decrease in hepatic cholesterol in RE-stimulated rats. Redistribution of cholesterol in RE-stimulated animals may be a mechanism whereby RE activity inhibits the hepatic accumulation of dietary cholesterol.

- 10943 EFFECT OF IONIZING RADIATION ON THE UPTAKE OF IRON BY LIVER CELLS IN VITRO (Hun.) Laszlo, M. (X-ray Clin., Debrecen, Hungary), A. Geza and P. Mozes. Magy. Onkol. 2:102-104, 1966.

Four groups of mature female rats received total-body Co^{60} irradiation (100, 200, 400, and 600 r.), 24 hr. before sacrifice. Liver cell suspensions (25×10^6 cells/ml) were incubated with an equal vol. of Krebs-Ringer-citrate buffer containing active Fe^{59} (60 $\mu g/ml$) at pH 7.0 for 15, 30, and 90 min. at $37^\circ C$, then centrifuged, washed in the cold, and counted. At 100 r there were no differences at any incubation time between cells of irradiated and normal rats. After 200 r, a moderate increase was seen at 15 and 30 min. incubation; the difference in uptake reached 2.3-4.8 μg after 90 min. After 400 r the differences were significant at each incubation time (3.5-10.4 μg); these differences increased to 7.5-12.5 μg after 600 r irradiation. This increase in iron binding capacity in vitro following total-body irradiation suggests the existence of factors other than bone marrow lesions that may also play a part in this process.

- 10944 ETHEREAL AND ACYL GLUCURONIDE FORMATION IN THE HOMOZYGOUS GUNN RAT. (E.) Javitt, N. B. (New York U. Sch. Med., N. Y.). Am. J. Physiol. 211(2):424-428, 1966.

In Wistar and homozygous Gunn (jj) rats, diphenylacetic acid was excreted in the bile as an acyl glucuronide and phenoldibromophthalein as ethereal mono- and diglucuronides; the rates of excretion of these glucuronides in the bile in both strains of animals were similar. The rates of excretion of phenoldibromophthalein and diphenylacetylglucuronides in the bile were much greater than the estimated max. rate of bilirubin conjugation in Gunn rats. It is suggested that the differences between these rat strains in bilirubin and nonbilirubin glucuronide conjugation (bilirubin conjugation is absent in the homozygous Gunn rat) are due to differences in the enzymes which catalyze their formation.

- 10945 FALL IN PLASMA CONTENT OF FREE FATTY ACIDS ASSOCIATED WITH SIGHT OF FOOD. (E.) Penick, S. B. (Cornell U. Med. Coll., New York, N. Y.), H. Prince and L. E. Hinkle, Jr. New Eng. J. Med. 275(8):416-419, 1966.

Volunteers of normal wt. were studied in 3 series of experiments to determine the plasma content of free fatty acids associated with the sight of food. Following a 5-hr. fast, blood samples were taken during a control period of varying duration; after the control period, subjects were presented with appetizing food which they had to look at for 1 min.; then another blood sample was taken. Subjects then took a small bite of food and an additional sample of blood was obtained 1 min. later. A fall in plasma free fatty acid conc. occurred within 1 min. after presentation of food. A double-blind randomized schedule of presentation allowed isolation of the food and (in 1 test) of the empty plate, as the inciting factor. It is suggested that the sight of food or its taste may possibly be a sufficient stimulus for some hungry people to cause their mobilization of free fatty acids to decrease in anticipation of a carbohydrate load, thus explaining the phenomena observed in these experiments.

HEPATIC METABOLISM

- 946 EFFECT OF BUNAMIODYL ON HEPATIC UPTAKE OF SULFOBROMOPHTHALEIN IN THE RAT. (E.) Berthelot, P. (Royal Free Hosp., London, England) and B. H. Billing. Am. J. Physiol. 211(2):395-399, 1966.
 en admin. in a single i.v. dose similar to that given for cholecystography in man (14 mg/100 g), bunamiodyl (Orabilix) caused an immediate decrease in the first slope (K_1) of the sulfobromophthalein (BSP) plasma disappearance curve in rats. This was dose-dependent, unrelated to changes in liver blood flow, and reversible within 6 hr. This change in K_1 BSP was not entirely explained by the action of bunamiodyl on biliary excretion; it was associated with a decrease in BSP content of the liver, suggesting that bunamiodyl impaired hepatic uptake of BSP. Bunamiodyl also caused a reflux of BSP from the liver into plasma. It is hypothesized that interference in hepatic uptake of BSP provides an explanation for transient BSP retention that may result from p.o. admin. of bunamiodyl in man.
- 947 LOCAL CONTROL OF HEPATIC ARTERIAL AND PORTAL VENOUS FLOW IN THE DOG. (E.) Hanson, K. M. (Indiana U. Med. Ctr., Indianapolis) and P. C. Johnson. Am. J. Physiol. 211(3):712-720, 1966.
 hemodynamic studies were made in over 100 experiments on the denervated, autoperfused dog liver in situ, using electromagnetic flowmeters. Data were collected on pressure-flow relationships in both vascular circuits, with and without simultaneous flow in the opposite system. Autoregulation of hepatic artery flow was seen in 60% of the artery pressure-flow experiments with intact portal inflow. Reduction of portal inflow by 67% gave an increased artery inflow and a 29% decrease in artery resistance; reduction in artery pressure resulted in decreased portal pressure and resistance, but portal inflow was unchanged. Elevation of hepatic venous pressure was accompanied by increased arterial resistance and decreased portal resistance. Arterial autoregulation, flow reciprocity and arterial resistance responses to hepatic venous pressure are explained on the basis of a common mechanism, a myogenic response of arterial resistance vessels. No portal venous autoregulation was seen.
- 948 ANTIDIURETIC HORMONE INACTIVATION BY ISOLATED PERFUSED RAT LIVER. (E.) Little, J. B. (Harvard Sch. Public Health, Boston), L. M. Klevay, E. P. Radford, Jr. and R. B. McGandy. Am. J. Physiol. 211(3):786-792, 1966.
 Characteristics of inactivation of U.S.P. posterior pituitary standard antidiuretic hormone (ADH) by the isolated rat liver were studied by 2 experimental methods: appearance of ADH from the circulating perfusate of continuously perfused livers, and fractional inactivation of ADH added to blood due to a single passage of the blood through the isolated liver. Liver ADH clearance was conc.-dependent; activations inactivated or extraction ratios in single-passage experiments ranged from 0.24 at 15-25 μ U ADH/ml plasma to 0.63 at 1000-5000 μ U/ml. It is concluded that the liver ADH clearance rate may be reduced by at least 50% in the physiological range of blood conc. No ADH activity was found in the bile of perfused livers; inactivation did not appear to depend on oxidative metabolism. It is concluded that continuous perfusion of the isolated liver results in the release of an ADH-inactivating factor into the blood perfusate.
- 949 ACTIVE TRANSPORT OF CHLOROTHIAZIDE INTO BILE. (E.) Hart, L. G. (NIH, Bethesda, Md.) and L. S. Schanker. Am. J. Physiol. 211(3):643-646, 1966.
 After i.v. admin. to rats with ligated renal pedicles, chlorothiazide (20 mg/kg) rapidly appeared in the bile in high conc. as the unchanged compound; 6% of the dose was excreted after 30 min., 20% after 90 min. Bile:plasma conc. ratio of chlorothiazide was 6.1-7.2; after correction for degree of plasma binding of the drug (90%), the ratio was 68-80. By increasing the drug dosage 10-fold, with a resultant 10-fold increase in plasma level, the proportion of the dose excreted in 90 min. declined about 50%, suggesting that the process of excretion is saturable. The carboxylic acid probenecid markedly depressed biliary excretion of chlorothiazide; chlorothiazide itself strongly depressed the excretion of p-acetylaminohippurate, a carboxylic acid which is actively secreted into bile. Although chlorothiazide contains neither the carboxylic nor sulfonic acid groups, it is apparently actively secreted into bile by the same process that secretes many carboxylic and sulfonic acids. Chlorothiazide also had significant choleretic activity in these experiments;

HEPATIC METABOLISM

the av. 90-min. bile vol. was 1.55 ml at the lower dose (20 mg/kg) and 1.91 ml at the higher dose (200 mg/kg), compared to 1.46 ml in untreated animals.

- 10950 RESPONSE OF ISOLATED LIVER TO ENDOTOXIN. (E.) Hinshaw, L. B. (VA Hosp. Oklahoma City), D. A. Reins and R. J. Hill. Canad. J. Physiol. Pharmacol. 44(4):529-541, 1966.

The vascular responses to Escherichia coli endotoxin (1-3 mg/kg) of the isolated denervated liver of dogs were studied during continuous perfusion via arterial and venous inflow vessels with blood from a dog or with a heart-lung apparatus. Admin. of endotoxin caused significant pressure increases in the hepatic artery and portal vein, as well as an increase in vascular resistance and liver wt. Vascular responses were not blocked by phentolamine or duplicated by inj. of suspected vasoactive agents. Responses to endotoxin and compound 48/80 (a histamine releaser, condensation product of p-methoxyphenethylmethylamine with formaldehyde) were not blocked by phenoxybenzamine, but the vasoconstriction caused by epinephrine and histamine was obliterated. Liver vascular response to endotoxin was duplicated by increasing the hepatic vein pressure by partial outflow obstruction. It is suggested that the intrahepatic venous system is the primary site of endotoxin action, with a subsequent myogenic response in the hepatic arterial segment.

- 10951 THE EFFECT OF 7-[2-HYDROXY-3-(N-2-HYDROXYETHYL-N-METHYLAMINO)PROPYL]-1,3-DIMETHYLXANTHINE, -PYRIDINE-3-CARBOXYLATE ON THE CHOLESTEROL CONTENT OF RAT LIVER. (Ger.) Struck, H. (U. Surg. Clinic, Cologne, Germany). Arzneimittelforschung 16(6):710-712, 1966.

Following admin. of a hypercholesteremia-producing diet for 17 days, Complamin was given to 7 male Sprague-Dawley rats in doses of 100 mg/kg/d p.o. Sacrificed on day 45 of the experiment, the treated animals had a mean total cholesterol content of 406 mg/100 g liver tissue, while controls fed the hypercholesteremia-producing diet only had a mean content of 555 mg/100 g. Histologically, the livers of the Complamin-treated rats showed significantly lower degree of fatty degeneration than those of the untreated animals.

- 10952 STIMULATION OF LIVER GROWTH BY DRUGS. II. BIOCHEMICAL ANALYSIS. (E.) Kunz, W. (U. Marburg, Germany), G. Schaude, H. Schimassek, W. Schmid and M. Siess. Excerpta Med. (Int. Congr. Ger.) (115):138-153, 1966.

Phenobarbital and halothane both produce liver enlargement but the mechanisms of wt. increase seem to be different. In mice treated with phenobarbital (200 mg/kg/day) and inhalation of halothane (0.5% preparation for 1 hr./day), individual cell components did not increase at a constant rate during the synthesis initial phase or during the following steady-state period during a 9-mo. study. Phenobarbital induced an increase of about 50% in all cell components except DNA, which increased at a lesser but still significant rate. The increase in lipids was almost exclusively confined to the phospholipids. This was true for all barbiturates and microsome inducing drugs of other chemical types. With halothane, the increase in RNA was proportionately smaller than that in protein; DNA increased about proportionally to protein. The predominant increase in liver lipids was in the neutral fats. Methoxyflurane produced the same effect. Liver enlargement was not caused solely by the increase of endoplasmic structures. The activity of reduced triphosphopyridine nucleotide (TPNH) oxidase rose rapidly by more than 500% after the beginning of treatment; other enzymes also increased in the early stages, but at different rates. One group of enzymes, which showed increases proportional to total liver wt. (and therefore no change in conc.) included the major enzymes in the Emden-Meyerhof series and the transaminases. A second group of enzymes, including lactic dehydrogenase (LDH), did not increase until the growth phase had concluded. The third group of enzymes showed a sharp rise in the initial stage of treatment; this group included triphosphopyridine nucleotide (TPN)-glutathione reductase, glucose-6-phosphate dehydrogenase, TPN-malic enzyme, and TPN-isocitric dehydrogenase. In contrast to the continuous increase of TPNH-oxidase, the activities of this group rose to a max., and then fell to normal or even subnormal levels at the conclusion of the growth phase. A different pattern of enzymatic activities in the liver was found during chronic treatment of mice with halothane. From the

evidence presented (especially in the treatment of mice with phenobarbital), the changes in metabolic levels (hence, changes in fixed contents) appeared to result from the redox state of the TPN system. The pentose phosphate shunt was clearly increased by phenobarbital, cyclobarbitol, and halothane. The biochemical changes induced by the carcinogens dimethyl- or diethylnitrosoamine were markedly reduced by simultaneous treatment with phenobarbital; fewer tumors occurred and these developed more slowly.

- 0955 THE EFFECT OF CHRONIC PHENOBARBITAL ADMINISTRATION ON SOME HEPATIC DRUG-METABOLIZING ENZYME ACTIVITIES IN THE RAT. (E.) Wilson, J. T. (U. Iowa Sch. Med., Iowa City) and J. R. Fouts. Biochem. Pharmacol. 15(8):1238-1241, 1966.

Male rats were inj. i.p. with phenobarbital sodium, 75 mg/kg/day for 2 days, then every other day for an additional 52 days. This dosage provided max. stimulation of the metabolic pathways studied. The 9000 g supernatant of the liver was used to study side chain oxidation of hexobarbital, hydroxylation of benzpyrene, the formation of p-aminobenzoic acid from p-nitrobenzoic acid, and the production of morphine from the O-dealkylation of codeine. All results were expressed as μ moles drug transformed/g liver/30 min. incubation period. Enzymatic transformation of hexobarbital in treated rats reached max. rates (300% of controls) after 4 days of treatment; this activity was maintained throughout treatment (60 days), then fell to control levels within 7 days after the end of treatment. The control animals remaining after 60 days were inj. with the standard amounts of phenobarbital and responded in the same way as the experimental animals. Prolonged phenobarbital admin. caused an increase in p-nitrobenzoic acid metabolism to over 200% of control levels after 4 days, to over 300% of controls after 4 days, and after 60 days, to more than 400% of controls. Benzpyrene hydroxylation was also enhanced by phenobarbital treatment, though not to the extent of the above reactions already described: it increased about 50% after 4 days of treatment, and after 60 days of treatment it rose about 10% more. The transformation of codeine to morphine was practically unchanged.

- 0954 MICELLAR MATERIAL IN HUMAN BILE. (E.) Bouchier, J. A. D. (Royal Free Hosp., London) and S. R. Cooperband. J. Gastroent. 19(3):253-258, 1966.
- Using isopycnic gradient ultracentrifugation in cesium chloride to isolate the micellar material in both gallbladder and liver bile, it was found that normal gallbladder bile contained micelles varying in molecular wt. from 65,000 to 75,000; that gallbladders having gallstones contained bile with micelles varying in wt. from 35,000 to 75,000; and that liver bile micelles varied from 11,000 to 20,000 in molecular wt. When the molecular wt. of the micelles was related to the conc. of the bile samples (using the sodium content of bile as the measurement of conc.), the molecular wt. increased with the bile conc., except at very high conc. of bile. The various components of the micelles, were as follows: cholesterol, 14.5%; phospholipids, 16%; bile salts, 66%; bile pigments, 3%; and protein, 0.5% of the material analyzed in the gradient. Even though these results indicate that some protein may be associated with the mixed lipid micelles in bile, it was possible to make "artificial bile" with stable micelles in the absence of protein. The gallbladder bile was taken from 4 patients with normal gallbladders and from 12 with pathological gallbladders having gallstones; the liver bile was obtained from common bile duct drainage following surgery for cholelithiasis.

- 0955 AUTONOMIC VASOMOTOR CONTROLS IN HEPATIC BLOOD FLOW. (E.) Ackroyd, F. W. (Harvard Med. Sch., Boston), M. Mito and W. V. McDermott, Jr. Am. J. Surg. 112(3):356-362, 1966.

Hepatic periarterial neurectomy in normal dogs produced a 15-25% increase in estimated hepatic blood flow (measured by Au⁹⁸ colloid) which was due to a 35% increase in hepatic arterial flow. In a dog whose hepatic blood flow had been reduced 53% by occlusion of the portal flow with an Eck fistula, hepatic periarterial neurectomy produced a 132% increase in the hepatic arterial flow which had the overall effect of increasing total hepatic blood flow to approx. 88% the normal resting value. Anemia tolerance curves improved to almost normal levels in these dogs. During the first postoperative mo., the survival rate of the latter was far greater than

those with just an Eck fistula; however, by the third postoperative month, the survival rates were similar. This increased hepatic blood flow effect caused by the neurectomy lasted about 4-6 wk. and could be reproduced by laparotomy and introduction of a 2% procaine nerve block at the site of the previous neurectomy. This temporary aspect is probably related to regeneration and budding of the splanchnic sympathetic fibers. In hemihepatectomized dogs with an Eck fistula and a periaarterial neurectomy, 20-40% liver regeneration occurred at the end of 1 mo., whereas, appreciable regeneration was not seen without the neurectomy.

- 10956 EARLY EFFECT OF ETHIONINE ON LIVER AFFINITY FOR IRON. (E.) Kinney, T. D. (Duke U. Med. Ctr., Durham, N. C.), N. Kaufman and J. V. Klavins. Nature (London) 211(5051):856-857, 1966.

Rats were tube-fed a diet containing 18% casein and received 0.5% d,l-ethionine 12 hr. before, 1, 2 and 3 days before killing, taking the last feeding 12 hr. prior to use. Livers were incubated in a Ringer soln. containing 10 mc iron⁵⁹ as ferrous sulfate, and the uptake of iron was determined by radioactivity measurement in a liquid scintillation spectrometer. Twelve hr. after ethionine feeding the liver uptake of Fe⁵⁹ was lower than the control group (2.44 against 2.81 cpm/g liver); after 24 hr. still lower (3.34 against 4.13 cpm/g liver); statistically identical after 48 hr. (3.79 against 3.91); and higher after 72 hr. (4.86 compared to 4.24). There was an observed decrease in liver RNA which coincided with the depression in liver affinity for Fe⁵⁹ in the ethionine-fed animals. The authors speculate that the decreased affinity for iron in the liver at an early interval of ethionine admin. is associated with depressed synthesis of apo-ferritin along with a general inhibition of protein synthesis.

- 10957 L-LYSINE DEHYDROGENASE DEFICIENCY IN A PATIENT WITH CONGENITAL LYSINE INTOLERANCE. (E.) Bürgi, W. (U. Bern, Switzerland), R. Richterich and J. P. Colombo. Nature (London) 211(5051):854-855, 1966.

A metabolic defect in lysine metabolism characterized by high plasma lysine levels found in a 3-mo.-old girl was attributed to enzymatic impairment in lysine degradation. Because of the lack of information on the enzymes of lysine catabolism in humans a search was made for an enzyme capable of degrading lysine and a hitherto unknown enzyme, L-lysine: NAD-oxido-reductase (deaminating) (trivial name: L-lysine dehydrogenase), was found. Homogenates of human liver were centrifuged at 1,500 x g (3 min.) and the supernatant used for assay of the enzyme. The following reaction was measured by recording increases in spectrophotometric absorption at 366 mμ:

The assay was found linear with time and enzyme conc., and the assay was performed on liver from the patient suffering from the lysine metabolism defect. The activity of this enzyme in the patient was 2.7 compared to approx. an av. of 10 μmoles min.⁻¹/liter homogenate for 3 control subjects.

- 10958 INHIBITION OF LIVER PHENYLALANINE AND TRYPTOPHAN HYDROXYLATING ENZYME SYSTEMS IN VITRO AND IN VIVO. (E.) Ross, S. B. (AB Astra, Södertälje, Sweden) and O. Haljasmaa. Acta Pharmacol. (Kobenhavn) 24(1):55-72, 1966.

Inhibition of phenylalanine- and tryptophan-hydroxylating enzyme systems from rat liver, using nicotinamide adenine dinucleotide (NAD), reduced NAD (NADH), NADH phosphate (NADPH), and 2-amino-4-hydroxy-6,7-dimethyl-5,6,7,8-tetrahydropteridine (DMPH4) as activators was studied. Tryptophan hydroxylation was inhibited completely and phenylalanine hydroxylation was partially inhibited by α-methyl-DOPA using NAD, NADH, or NADPH as cofactors (50% inhibitory conc. for the tryptophan reaction in each case was 3×10^{-7} M), but DMPH4-activated hydroxylation was affected only slightly. Esculetin and α-propyl-3,4-dihydroxyphenylacetamide (H 22/54) inhibited hydroxylation of both amino acids with all the activators used, but DMPH4-activated reactions were less sensitive than reactions activated by NAD, NADH, or NADPH. Esculetin was a competitive inhibitor and H 22/54 a noncompetitive inhibitor of DMPH4-activated hydroxylation of phenylalanine. Aminopterin inhibited the hydroxylation of both amino acids using NAD and its derivatives as cofactors, at about equal conc. (about 10^{-6} M caused 50% inhibition of tryptophan hydroxylation), but had no

effect on DMPH4-activated reactions. Tryptophan hydroxylation in vivo, using NAD DMPH4 as activators, was studied in mice. Esculetin (100 or 200 mg/kg i.p.), methyl-DOPA (200 or 800 mg/kg i.p.), and aminopterin (100 mg/kg i.p.) antagonized DMPH4-activated hydroxylation but had much less effect on DMPH4-activated reactions; 2/54 (100 or 200 mg/kg i.p.) was the most potent inactivator of the DMPH4-activated reaction.

59 CAUSES OF THE CHANGE OF URINARY NA/K AND Cl/NA RATIOS AFTER A MEAL. CHANGES OF SERUM ELECTROLYTE CONCENTRATIONS OF HEPATIC AND PORTAL VEINS AND OTIC ARTERY AFTER A MEAL IN RABBITS. (Jap.) Watanabe, A. (Inst. Sci. Labor, Tokyo), I. Suzuki, R. Nishizaki and H. Saito. Rodo Kagaku (J. Sci. Labor) 42(6):448-453, 1966.

Following a 24-hr. fast, samples of blood were taken from a group of adult male rabbits, which were then subdivided into an experimental group, which received a standard meal and a control group, receiving water only. Second blood samples were taken from the experimental group (which was itself subdivided) as follows: Group 1, 5 min.; Group 2, 50-80 min.; Group 3, 110-140 min.; and Group 4, 180-240 min., after the meal. Samples were taken from hepatic and portal veins, and hematocrit and serum sodium, potassium and chloride were determined. There was no significant difference in serum sodium, potassium and chloride, and Na/K and Cl/Na ratios in the otic arteries in either the experimental or control groups before or after the meal. No significant difference was found in Na/K ratio of liver ash between controls and the experimental group. In the experimental group, serum K of hepatic vein was lower and its Na/K ratio higher than the same measurements for portal vein. No difference was noted among the four groups. Hematocrit of otic venous blood was always higher than that of portal blood, but no significant difference was found between the experimental and control groups. Hematocrit of portal and blood samples taken from the otic artery was lower than the first sample in the experimental group, but the control showed no difference between the first and second blood samples.

60 BIOSYNTHESIS OF GLYCOLIC ALDEHYDE AND GLYCOLIC ACID IN THE LIVER UNDER THE EFFECT OF VITAMIN A-ACID. (Rus.) Leutskaia, Z. K. (Chernovtsy State U., USSR), E. N. Liubovich and K. M. Leutskii. Ukr. Biokhim. Zhur. 38(3):309-313, 1966.

Biosynthesis of glycolic aldehyde and glycolic acid in the rat (males, 50 g wt.) was studied in vitro in the normal state and with avitaminosis A under the effect of vitamin A-acid is reported. The effect of another acid involved in glycine metabolism (ketoglutaric) as well as of a solvent served as a control. Determinations were carried out before and during incubation, which lasted 20 and 75 min. The actual increase in glycolic aldehyde under the effect of vitamin A-acid was 0.589 in 20 min. and 0.965 $\mu\text{mol/g}$ in 75 min. in the control animals, and 0.436 in 20 min. and 0.703 $\mu\text{mol/g}$ in 75 min. in the avitaminosis A animals. The increase in glycolic acid under the effect of vitamin A-acid in the control animals was 3.9 and 4.5 $\mu\text{mol/g}$ in 20 and 75 min., resp.; in the avitaminosis A animals, 8.7 and 2.9 $\mu\text{mol/g}$ in 20 and 75 min. resp. The actual increase in glycolic aldehyde under the effect of α -ketoglutaric acid was 0.080 and 0.074 $\mu\text{mol/g}$ in 20 and 75 min., resp.; for the avitaminosis A animals, 0.374 and 0.076 $\mu\text{mol/g}$ in 20 and 75 min., resp. The increase in glycolic acid under the same conditions was 0.3 and 0 in 20 and 75 min., resp., for controls; 1.8 and 1.6 $\mu\text{mol/g}$ in 20 and 75 min. for the avitaminosis A animals. It is believed that vitamin A-acid is involved in the biosynthesis of glycolic aldehyde and glycolic acid in experiments conducted in vitro in the normal state and in avitaminosis A.

61 ROLE OF LIVER IN REGULATING DISTRIBUTION AND EXCRETION OF MANGANESE. (E.) Papavasiliou, P. S. (Brookhaven Nat. Lab., Upton, N. Y.), S. T. Miller and G. C. Cotzias. Am. J. Physiol. 211(1):211-216, 1966.

Animals were studied after receiving a standard laboratory diet containing 32.5 μg Mn/g or milk containing 36 μg Mn/g for 1-2 wk. In some groups the common bile duct was ligated; in some the lower segment of the rectum was also ligated. ^{54}Mn was inj. i.v. In other groups the hepatic artery and portal vein were

clamped for 10 min. following inj. of $Mn^{54}Cl_2$. Rectal obstruction abolished total-body loss of Mn^{54} in both Mn-loaded and jaundiced rats. Bile duct ligation only diminished radioisotope excretion which was taken to show that several gastrointestinal routes excrete Mn. Excretion of intraportally inj. Mn was rapid; the effect of bile duct ligation was enhanced. Biliary ligation induced a rise, then a decline in conc. of Mn^{54} in the liver; the conc. of Mn^{55} was increased. This effect was linked to absorption and rapid reexcretion of the metal. The data indicated that bile formation constitutes the main regulatory route for Mn under ordinary conditions; under conditions of overloading, auxiliary gastrointestinal routes participate.

- 10962 THE DEVELOPMENT OF ARGINASE AND ORNITHINE-TRANSCARBAMYLASE ACTIVITIES IN THE LIVER OF RATS. (E.) Illnerová, H. (Inst. Physiol., Czech. Acad. Sci., Prague). Physiol. Bohemoslov. 15(1):19-22, 1966.
Periodic determinations of hepatic ornithine transcarbamylase activity from birth to 40 days of age in Wistar-Konarovice rats fed standard (24% protein) diets showed a gradual increase up to day 14 with a more rapid increase thereafter up to days 20-25 when the levels were essentially those of adult rats. Arginase activity remained unchanged up to day 14 and then increased rapidly to an adult max. at days 24-30. The rapid increase in these activities after 14 days occurs at a time when the eyes normally open and solid food is first consumed.

- 10994 STUDIES ON THE ENZYMES OF HUMAN BLOOD. XII. ROLE OF AN ARYLESTERASE FRACTION FROM LIVER IN FAT METABOLISM IN MAN. (Ger.) Pilz, W. (Farbenfabriken Bayer AG, Leverkusen, Germany), H. Hörlein and E. Stelzl. Zschr. Physiol. Chem. 345(2/3):65-79, 1966.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

- 995 NORMAL VALUES OF A PHOTOMETRIC AMYLASE DETERMINATION IN SERUM, URINE, DUODENAL JUICE, AND SALIVA. (Ger.) Goll, K. H. (Unter den Linden Diagn. Med. Inst., Berlin). Deutsch. Gesundh. 21(23):1078-1081, 1966.
- Results of α -amylase determinations by the photometric method of Richterich were subjected to statistical analysis in an attempt to arrive at clinically meaningful values. A total of 1088 duplicate tests were made on normal specimens of serum (14), urine (333), duodenal juice (190), and saliva (51). The av. normal value is taken as the 50% reading with a scatter between +1 and -1 standard deviations (-95%). Thus, the normal mean (50%) serum value is given as 1150, with a normal range ($\pm 10\%$) between 320 and 2200 and pathological values below 142 or above 3100. Values for urine (as above) were 4000, 1000-9200, below 560, and above 12,800, resp. For duodenal juice (in 103) the values were 880, 160-2400, below 80 and above 2870, sp. For saliva (in 103) the values were 140, 77-620, below 54 and above 1040, sp.
- 996 MODIFICATION OF THE TECHNIC OF CLAUDE FOR THE FRACTIONATION OF HUMAN LIVER TISSUE HOMOGENATES. (It.) Scaduto, P. (U. Palermo, Italy), G. A. Cerasola, E. Laudicina, G. Furitano and G. Bompiani. Fegato 12(1):80-88, 1966.
- Using Claude's ultracentrifugation technic (sedimenting the nuclear fraction at 100 g, the mitochondrial at 600 g and the microsomes in the last fraction) and 0.25 M sucrose medium, the resulting isolated liver fractions, examined under the electron microscope, were heavily contaminated. Modifications were made; the liver homogenates were spun at 600 g for 15 min. to separate the nuclear fraction; the supernatant was suspended in sucrose and centrifuged 3 times (17,000 g for 20 min., then 17,000 g for 20 min., then 6,000 g for 20 min.) to isolate the mitochondrial fraction. The supernatants of the second, third and fourth centrifugations were centrifuged at 25,000 g for 20 min. to give the microsomal fraction. Homogeneous fractions were quite evident with this method; they were not contaminated by elements of the preceding and following fractions.
- 997 LOMOTIL IN TREATMENT OF POST-VAGOTOMY DIARRHOEA. (E.) Collins, C. D. (U. Dept. Surg., Roy. Infirm., Sheffield, England). Brit. Med. J. 2(5513):560-561, 1966.
- 154 patients who had undergone total vagotomy with drainage, 23 had diarrhea sufficiently severe to be subjects of double-blind study with Lomotil (diphenoxylate 5 mg and atropine sulfate 0.05 mg), codeine phosphate (15 mg), and a sucrose placebo. Lomotil proved to be a satisfactory constipating agent, but had no significant advantage over codeine phosphate and was judged to be of little value either the prophylaxis of sudden episodic attacks or the treatment of more continuous postvagotomy diarrhea. Side effects were noted in 5 patients, including dryness of the mouth, nausea with headaches, vomiting, and dizziness.
- 998 SILICONE IN THE PREVENTION OF INTRAPERITONEAL ADHESIONS IN DOGS. (E.) Del Rosario, V. C. (Baylor U. Med. Ctr., Dallas, Tex.), G. H. Prater and J. M. Garvey. Am. Surg. 32(9):638-640, 1966.
- Six adult mongrel dogs underwent laparotomy with removal of a 2-cm strip of serosa lining from the antimesenteric wall of the entire small intestine, from the distal ileum to the duodenum. Hemostasis was obtained by covering the intestine with a firm moist pack for 10 min. In control animals the intestine was simply replaced into the peritoneal cavity, and the incision closed in layers. The other dogs received medical-grade silicone fluid (viscosity 350 centistokes) by instillation into the peritoneal cavity of test animals; all denuded areas of the intestine were covered with this substance prior to closure of the wound. A dose of 6 ml/kg was sufficient to coat all peritoneal organs, with extra fluid free in the peritoneal cavity. Postoperatively all animals were given penicillin. A second laparotomy was performed 2 mo. later to compare the extent of adhesions in experimental and control animals. No significant difference was noted in the nature and extent of peritoneal adhesions between the 2 groups, which were extensive and dense, in all

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

dogs: silicone fluid was present at the second exploration. The fluid, although turbid in some animals, was sterile. Silicone fluid did not affect healing of the laparotomy.

- 10999 A SIMPLIFIED METHOD FOR THE DETERMINATION OF ORNITHINE CARBAMYL TRANSFERASE (Rum. 81-82) (Eobrescu, I. Turcu, and A. Cristescu. Med. Intern. (Bucur.) 16(3):975-981, 1966)

A detailed description of an extensive modification of the Morett method is given. In effect, it eliminates its entire modification step, changes the order of the phenol and microbromsulphuric acid reactions (the result is a clear blue color), and adapts the whole procedure to photometric readings, thus eliminating the use of spectrophotometers. As tester of 40 normal and 50 pathological sera, the test duplicated the original within a limit of 0.1%. Normal values are between 0.1-0.2 $\mu\text{g}/100\text{ ml}$ serum, and pathological values between 1-4 $\mu\text{g}/100\text{ ml}$ in severe cases; 0.1-0.2 $\mu\text{g}/100\text{ ml}$ serum.

- 11000 FACTORS AFFECTING THE INHIBITION OF PHOSPHOFRUCTOKINASE ACTIVITY OF Schistosoma mansoni BY TRIVALENT ORGANIC ANTIMONIALS (E.) Guesing, L. John, H. H. H. Baltimore, Maryland, and J. H. Blocher. Pharmacology 15(6): 1197-1211, 1966

Phosphofructokinase (PFK) activity in extract from adult Schistosoma mansoni remained stable for at least 3 hr. at 0°C. Immediately prior to assay, the homogenate was diluted 6-fold in glycidylglycine buffer. PFK activity was measured spectrophotometrically at room temperature after reaction products had been converted to triose phosphates. Because ammonium and sulfate ions affected PFK activity, enzyme preparation was dialyzed against 0.05 M glycidylglycine buffer (pH 7.4). In addition to the PFK studies, phosphatase levels were investigated, especially fructose-6-phosphate (F6P), the substrate of PFK; the inhibition of schistosomal PFK activity and the anti-schistosomal action of trivalent organic antimonial compounds *in vivo* were compared. As in the case of PFK from numerous other tissues and organisms, inhibition of PFK activity of S. mansoni by high concentrations of adenosine triphosphate (ATP) was increased by citrate. PFK was also reduced by increasing concn. of F6P, and in varying degrees by adenosine mono- and diphosphate, cyclic 2',5'-adenosine monophosphate, and inorganic phosphate. ATP decreased the affinity of schistosomal PFK for F6P; these compounds which reversed the inhibitory effect of high ATP concn. increased the affinity of the enzyme for F6P. Several differences between the properties of PFK of mammalian and schistosomal origin are noted, including the 60-85-fold greater sensitivity of schistosomal PFK to the inhibitory effects of trivalent organic antimonial compounds. Inhibition of PFK activity by antimonials was reversed by increasing the concn. of F6P; inhibition was enhanced by high concn. of ATP, and reduced by the ions which increase the affinity of this PFK for F6P. Antimonial compounds seemed to inhibit the PFK by competing with F6P for a site on the enzyme molecule. Ester levels increased in S. mansoni in the presence of antimonial compounds.

- 11001 LAPAROSCOPIC CONTROL STUDY OF THE RESORPTION OF DYE SOLUTIONS UPON INTRAVENOUS, INTRA-ABDOMINAL AND INTRASPLENIC ADMINISTRATION. (CHROMO-LAPAROSCOPY II.) (Hun.) Wittman, I. (Balassa Hosp., Budapest, Hungary). Z. Aszód; and L. Papp. Orv. Hetil. 107(34):1598-1601, 1966

Color changes obtained in abdominal organs of normal subjects and dogs, their appearance, duration and disappearance (excretion), were studied in the gallbladder (content, surface, and blood vessels), stomach, liver, kidney, and intestines after i.p. and intrasplenic admin. of a number of dyes and drugs. Human volunteers received acridine orange, Congo red, methylene blue, indigo carmine, and rose bengal; dogs received in addition fluorescein and its sodium salt, rhodamine B, thioflavin T, thiazo-yellow, chloroquine, chlortetracycline, and Endocistobii (conc. used for intrasplenic admin. are given; those for i.v. and i.p. are referred to in another communication). The dyes appeared in the gallbladder and could be visualized after a few min. in most cases (2-4 min.); return to the normal coloration of the gallbladder occurred within as little as 15-20 min.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

11002 ESTIMATION OF SERUM PEPSINOGEN. (E.) Ilic, V. (Radcliffe Infirm., Oxford, England) and G. H. Spray. Gut 7(4):415-419, 1966.

A modification of the Bock method for estimating serum pepsinogen is described which uses hemoglobin as the substrate. The advantage of this modified method is that it requires less serum for testing, the absorption may be read at 280 m μ (which eliminates the tedious use of Folin-Ciocalteu reagent) and the serum can be frozen and stored for 10 mo. without loss of activity. In 135 control subjects, the mean value was 833 with a range between 310-2140 μ g tyrosine/ml serum in 24 hr.; for 137 patients with pernicious anemia, the mean was 373 with a range of 130-910. Since some of the values of these 2 groups overlap, this estimation would not be useful for individual diagnosis, but rather as a screening test for the study of large groups. The mean value for 10 patients whose gastric biopsy specimens showed superficial gastritis was 786 μ g tyrosine/ml serum in 24 hr., which was slightly higher than the mean for 8 patients with normal gastric mucosa (710). In 7 patients with atrophic gastritis the mean was 464 as compared with 363 for 17 patients with gastric atrophy, which was almost the same as that found with pernicious anemia.

11003 QUANTITATION OF GASTROINTESTINAL BLEEDING BY USE OF A LARGE VOLUME SCINTILLATION DETECTOR. (E.) Anderson, E. T. (U. Illinois Coll. Med., Chicago), M. Passovoy and F. E. Trobaugh, Jr. J. Nucl. Med. 7(8):612-619, 1966.

A clinically practical method for detecting and quantitating blood in feces is described which is convenient for the patient, inoffensive in the laboratory, relatively inexpensive and uses disposable containers. It involves an essentially closed-system of stool collection and radioassay which requires only 1 specimen transfer and is coupled with sodium chromate⁵¹-labeling of RBC. A large vol. scintillation detector is utilized which insures constant geometry and permits a sensitive radioassay (estimated at 25% efficiency for Cr⁵¹) of the entire specimen. All stools in a 24-hr. period are passed directly into a tin container which is refrigerated in the patient's room. In general, the collection continues over a 5-day period. Prior to this the patient's RBC are tagged with Cr⁵¹ by incubating 6 ml of anticoagulated blood with 1.5 μ c of Cr⁵¹/kg of body wt. for 30 min. and then, after resuspension in saline, reinjected in the patient. The collected stools are mixed by external agitation, transferred to low potassium glass jars and counted (the max. counting error of this system was 2%). An av. daily blood loss of 0.489 ml (ranging from 0.02-1.44 ml) was detected in 32 stool specimens taken from 7 patients with no evidence of gastrointestinal disease.

11004 AN IMPROVED CANNULA FOR EXPERIMENTAL GASTROINTESTINAL FISTULAS. (E.) Hudock, J. J. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.), R. Barthers and S. Denecko. J. Surg. Res. (Boston) 6(6):262-264, 1966.

The authors have modified the original gastrointestinal cannula of Thomas, both in materials and in details of construction. After testing an array of different materials, Rexolite, a styrene copolymer, acid- and alkali-proof, and chip and breakage resistant, was found to be excellent for the inner section of the cannula which is placed within the intestine. The outer flange and cap were made of stainless steel, type 302-304. These materials can be sterilized by autoclaving or boiling. A "holder-wrench" was also devised with a brass insert to fit an internal slot in the inner styrene section of the cannula to maintain this section in a fixed position, while the outer stainless steel flange is firmly tightened by rotating it clockwise. The cap was designed for easy removal; its depth was increased, and 2 sides of the outer portion were squared so that an adjustable wrench can be used on it for removal if a screwdriver in the slot, also provided, will not turn it. Cannulae of this construction have been maintained in the same animals for periods up to 5 yr. during which numerous experiments have been performed. Some surgical directions for the insertion of these cannulae are also included.

11005 RESPIRATORY KYMOGRAPHY IN DIFFERENTIAL DIAGNOSIS BETWEEN ACUTE ABDOMINAL AND ACUTE PULMONARY CONDITIONS. (E.) Schmidt, S. (St. Erik's Hosp., Stockholm, Sweden). Acta Chir. Scand. 132(1/2):143-153, 1966.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

Kymographic examinations were made of 30 normals, 149 acute abdominal cases, and 47 acute pulmonary cases. The kymograph consisted of 2 lead plates, each with a 1-mm slit which could be positioned over one side of the diaphragm and lower half of the chest. A 30 x 40 cm film was exposed by a X-ray source below the patient while moving (5.5 cm/15 seconds) from the patient's left to his right, yielding a record of movement of a 1-mm segment of the diaphragm and lower chest. Normally a record was made of ordinary and deep breathing. The tracing of a diaphragmatic respiratory cycle is a regular slightly asymmetric steep wave; approx. amplitude was 2-4.5 cm. The costal waves were relatively flat with direction opposed to the diaphragmatic waves; the av. amplitude was 2-5 mm. Acute abdominal cases showed 80% of restriction of diaphragmatic movements, the waves in more than half showed a blunted apex. The abdominal cases showed 60% of costal respiratory restriction. In the acute pulmonary patients amplitude was reduced in 60% of the cases, the movement waves were normal in 60% and step formed in 40%. In these patients the costal amplitude was reduced in 80%. It is concluded that the method is useful in differential diagnosis between acute abdominal and acute pulmonary conditions. Abdominal disease mostly influences diaphragmatic respiration; pulmonary conditions mostly cause restriction of costal respiration.

GASTROINTESTINAL DISEASES

GENERAL

- 11025 SOME SUBSTRATE AND ENZYME LEVELS IN ILEUS. (Ger.) Herfarth, C. (U. Marburg, Germany) and I. Staib. Bull. Soc. Int. Chir. 25(2):101-107, 1966.

Lactate, pyruvate, and glucose levels in blood and glutamate oxalacetic transaminase (GOT), glutamate pyruvate transaminase (GPT), aldolase (ALD), lactate dehydrogenase (LDH), malate dehydrogenase (MDH) and glutamate dehydrogenase in the serum of dogs, and in muscle and liver tissue of rats were studied after experiments induced high and low intestinal obstruction (both strangulation and occlusion obstructions). Glucose levels showed no difference in high or low ileus; lactate and pyruvate changes in either occlusion or strangulation ileus were uncertain, except for a lactate increase (not significant) in the first phase of the latter. The redox quotient (lactate/pyruvate) stays around 10, except for a few animals in the terminal stages of blood vol. reduction where it increases. Enzyme activity in occlusion ileus shows only minor increases compared to the base-line values (levels on days 2-4 after surgery preparatory for ileus production). Only GPT increases in high occlusion ileus resulting in a Ritis quotient (GOT/GPT) much below 1. This can also be seen in cases of high strangulation ileus, but the changes are not quite significant. However, in low strangulation ileus there is an excessive rise in GOT, GPT, and MDH, but only in animals which develop gangrene. The source of transaminases in these conditions is the liver; it is also responsible for an increase of LDH which follows the above sequence. Enzyme patterns in muscle and liver show significant changes only in low strangulation ileus. LDH, MDH, and (to a lesser extent) GOT are significantly increased in both liver and muscle tissue, reaching 100%, 70%, and 70%, resp., in the latter. ALD and GPT remain constant or decrease slightly; the picture as given in low strangulation ileus is compatible with severe liver damage.

- 11026 MICE AND MONKEYS AS ASSAY ANIMALS FOR Clostridium perfringens FOOD POISONING. (E.) Weiss, K. F. (U. Wisconsin, Madison), D. H. Strong and R. A. Groom. Appl. Microbiol. 14(4):479-485, 1966.

The toxicity of various strains of Clostridium perfringens was studied in mice and young rhesus monkeys by feeding spores and vegetative cells in combination with meat or starch paste. Some of the preparations were admin. to the monkeys by stomach tube; other preparations were admin. in gelatin capsules treated with formaldehyde so that the contents were released in the intestine. The results were inconclusive. Diarrhea occurred only infrequently in both species, regardless of the substance fed or the mode of admin. The changes in intestinal passage time was not great, although there was a tendency toward reduction in time as the bacterial load was increased. Phosphorylcholine had little, if any, effect in reducing intestinal passage time of mice or monkeys. No procedures explored in these experiments were satisfactory as a means of animal assay for food poisoning strains of C. perfringens, as typical symptoms did not appear with regularity.

- 11027 INTESTINAL BLOOD LOSS: A FACTOR IN CALCULATIONS OF BODY IRON IN LATE INFANCY. (E.) Elian, E. (Tel-Aviv U. Sch. Med., Israel), S. Bar-Shani, A. Liberman and Y. Matoth. J. Pediat 69(2):215-219, 1966.

One μC $\text{Na}_2\text{Cr}^{51}\text{O}_4/\text{kg}$ body wt. was used to tag RBC in hospitalized infants ranging from 2-17 mo. in age. Controls (25) were free of any evidence of infection or diarrhea, 9 infants were examined during acute infections, 10 were examined during acute gastrointestinal infections including diarrhea. Collection of feces was started 24 hr. after reinj. of labeled blood. Counts were made of 5 samples of each stool in a well-type scintillation counter. Apparent blood loss in the stool was calculated by dividing total stool radioactivity by the av. radioactivity/ml circulating blood on the first and last days of collection. Apparent blood loss in the control group ranged between 0.17 and 2.5 ml/day, an av. of 0.64 ml/day. The acute infection group ranged from 0.2 to 0.9 ml/day, av. 0.43 ml/day; the difference was not significant. Blood loss in the gastroenteritis group ranged from 0.7 to 4.8 ml/day, av. 1.85 ml/day. The values of this group were highly significant from the other two. No significant differences were found in hemoglobin

levels. The benzidine test was positive in 89% of the third group of patients compared to 23 and 33% in groups 1 and 2. It was concluded that intestinal bleeding of the magnitude found in these infants could over a period of mo. account for the loss of iron in amounts equal to a large proportion of body iron in late infancy.

- 1028 EARLY SYMPTOMS AFTER EXPERIMENTAL INFECTION OF MAN WITH Ancylostoma braziliense VAR. ceylanicum. (E.) Wijers, D. J. B. (Inst. Trop. Hyg., Amsterdam, The Netherlands) and A. M. Smith. Trop. Geogr. Med. 18(1): 48-52, 1966.

Experimental cutaneous infection of 8 volunteers with a strain of Ancylostoma braziliense var. ceylanicum which was obtained from the feces of a man naturally infected in West New Guinea and subsequently passed through 7 dogs over a period of 18 mo. caused itching, papular eruptions at the site of application and eventual abdominal discomfort. A counted number of investive larvae were dispersed in sterile soil in a watch glass and this was attached to the arm for 12 hr. During the following 2 days some papules the size of a pin's head developed within the area of application. These generally disappeared within 3 wk. Between 15-20 days after infection, all volunteers experienced abdominal distress: an unpleasant sensation of tenderness and pressure in the upper abdomen, especially in the left upper quadrant and the epigastrium. Belladonna provided temporary relief, but an antacid was ineffective. Four volunteers who suffered most took a dose of 1 g of Alcopar 8-11 days after the onset of abdominal symptoms. All improved, but were only totally free of symptoms after 3-4 wk. Hookworm eggs were detected in the feces of all 3-5 wk. after larval application; the earliest positive finding was after 21 days. In 7 of the participants the percentage of eosinophils was markedly increased (19-44%).

- 1029 EFFECT OF CHLOROQUINE AND EMETINE ON RAT LIVER MICROSOMAL ENZYME SYSTEM. (E.) Kale, A. K. (B. J. Med. Coll., Poona, India), G. V. Joglekar and J. H. Balwani. J. Postgrad. Med. 12(2):88-90, 1966.

Chronic admin. of either chloroquine or emetine (antiamebic agents which selectively concentrate in liver parenchyma) to male rats caused a significant prolongation of hexobarbitone-induced sleeping time and markedly depressed urinary excretion of ascorbic acid. Both of these measurements are parameters used for testing microsomal enzyme activity in the liver; thus, both drugs significantly inhibited this activity. Chloroquine phosphate (100 mg/kg) or emetine hydrochloride (10 mg/kg) was admin. by intragastric tube to 15 rats for 15 days and ascorbic acid excretion and hexobarbitone sleeping time (100 mg/kg i.p.) were measured before and afterwards. Since ascorbic acid is synthesized in rats from l-gluconogalactone, these drugs could possibly produce toxic effects if admin. concurrently with other drugs undergoing glucoronide synthesis, such as chloral hydrate, antipyrine, salicylates, phenacetine, avertin, chloramphenicol and certain steroids.

- 1030 DYSPEPSIA, DUODENITIS AND HOOKWORM INFECTION. (E.) Rowland, H. A. K. (London Sch. Hyg. Trop. Med., England). Trans. Roy. Soc. Trop. Med. Hyg. 60(4):481-485, 1966.

Twenty patients with hookworm infection who also had severe anemia complained of abdominal pain unlike that described as typical for peptic ulcer, and their radiographs resembled those described for non-ankylostomal duodenitis. Neither feature was closely related to hookworm load. The upper abdominal discomfort which was present in 15 patients was described as vague, intermittent, colicky and only occasionally severe. In all of the 12 patients who showed abnormalities on their radiographs a coarsening of the duodenal mucosa was seen. Dilatation of the duodenal bulb or the duodenum generally was seen in 7 patients. The cap itself was spastic or showed a spiky outline in 4 and in 4 the barium gushed through the duodenum. Heavy hookworm loads produced little mucosal change; in fact, duodenal biopsies were never markedly different from normal. Some correlation seemed to occur between the hemoglobin conc. and the severity of symptoms, as well as the appearance of an abnormal radiograph.

GENERAL

- 11031 SERUM HAPTOGLOBIN IN KWASHIORKOR. (E.) Khalil, M. (U. Alexandria, Egypt), M. K. Badr-El-Din and A. S. Kassem. *J. Trop. Med. Hyg.* 69(7): 150-152, 1966.

Serum haptoglobin was found to be low in all 25 children with kwashiorkor; complete ahaptoglobinemia was present in 2 cases. They all had a history of inadequate breast feeding with supplementary starch or rice water and repeated attacks of gastrointestinal disturbances. In these cases (ages from 8 mo.-3 yr. 3 mo.) the mean hemoglobin-binding capacity was 53.4 mg/100 ml serum, whereas the mean in 98 children over 6 mo. of age was 109.3 mg/100 ml serum. In the 25 cases of kwashiorkor, thymol turbidity was almost normal in 14 cases and elevated in 11. Six cases had a serum protein level below 4 g/100 ml and the mean hemoglobin binding capacity level of these 6 was an extremely low 13.8 mg/100 ml serum. A follow-up study of 6 treated cases showed that the level of hemoglobin binding capacity returned to normal with clinical recovery and the plasma protein level and thymol turbidity improved as well. No correlation was found between the level of serum haptoglobin and the RBC sedimentation rate; a small rise in the latter was seen only in cases with secondary infection. These data would indicate that liver dysfunction may be a contributory factor in the lowering of the serum haptoglobin in kwashiorkor.

- 11032 FEMORAL HERNIA IN CHILDREN. (E.) Lickley, H. L. A. (Hosp. Sick Child., Toronto, Canada) and G. A. Trusler. *J. Pediat. Surg.* 1(4): 338-341, 1966.

Between 1925-1965, 40 cases of femoral hernia were recorded at this hospital, which represented only 0.4% of the total hernias (about the inguinal region) seen during this time period. Thus femoral hernia in children is relatively rare. The children usually presented with an asymptomatic soft swelling in the groin, which was sometimes tender. Seven had crampy abdominal pain associated with anorexia and vomiting. The duration of symptoms, extending from a few days to 7 yr. did not seem to be related to the incidence of incarceration. In 4 children the hernia was irreducible; incarceration occurred in 2 others and strangulation in one. The children's ages ranged from 3 mo.-13 yr; 16 children were under 5 yr. Three children had an inguinal hernia in addition to the femoral hernia. It is noteworthy that 12 children had a bilateral inguinal herniotomy performed 3 wk.-4 yr. prior to the appearance of the femoral hernia. In 6 of these patients the inguinal hernia had been unexpectedly small, suggesting an error in diagnosis. Thirty-one of the hernial sacs were suture-ligated at the base, 15 through a femoral canal approach and 16 after the sac had been delivered into the inguinal region. In addition, a repair was attempted in all but 2 cases which most frequently was an attempt to narrow the femoral canal. The known recurrence rate in this series was 7.5%, all of which occurred in children in whom the femoral canal had not been closed.

- 11033 GIARDIASIS IN ADULTS. INCIDENCE, SYMPTOMATOLOGY AND ABSORPTION STUDIES. (E.) Antia, F. P. (B. Y. L. Nair Charitable Hosp., Bombay, India), H. G. Desai, K. N. Jeejeebhoy, M. P. Kane and A. V. Borkar. *Indian J. Med. Sci.* 20(7):471-477, 1966.

In 4720 patients (age 10-70 yr.), the incidence of *Giardia lamblia* (*Giardia intestinalis*) was 6.4% in adults, but 23.3% in those with chronic diarrhea. Presenting symptomatology in 285 adults included abdominal pain (49%), or diarrhea (14%) or both (25%); they were exacerbated by certain foods, such as milk and spices. Symptoms were absent in 14 adults (5%). Duodenal intubation revealed abundant motile flagellates. Fat, glucose, lactose, folic acid, and vitamin B₁₂ absorption was variable; small intestine biopsy revealed partial villous atrophy in some patients. The immediate response to 5-day courses of p.o. chloroquine (600 mg/day), mepacrine (300 mg/day), or acranil (300 mg/day) was good, but cysts reappeared on stool examination in 3-4 wk.; a more prolonged treatment is suggested for long-term cure. Studies in children are not described.

GENERAL

- 1034 ROUSSY-LEVY SYNDROME WITH FUNCTIONAL IMPAIRMENT AND ANOMALIES OF GASTRO-INTESTINAL TRACT. (E.) Pruzanski, W. ('Asaf Harofe' Gov. Hosp., Zerifin, Israel). Confin. Neurol. 26(6):495-502, 1966.
67-year-old man with Roussy-Levy syndrome (a variant of Friedrich's ataxia) associated with valvular syndrome, sliding diaphragmatic hernia, megacolon-sigmoid and hypopharyngeal diverticulum, and malabsorption syndrome with sprue-like manifestations is reported. A familial study revealed cases of mental illness or inefficiency, epilepsy, an abortive form of Friedrich's disease and nerve deafness on one side, and on the other diarrhea, dolichocolon, constipation, and malabsorption syndrome. The patient's parents were uncle and niece; 3 of his 4 siblings had various neurological symptoms, his son had dolichocolon, and his daughter nerve deafness with chronic constipation. Possible relationship(s) between gastrointestinal disturbances and neurological heredo-familial disease are discussed. This is thought to be the first such case of associated symptoms reported in the medical literature.
- 1035 AMPICILLIN FOR PERSISTENT TYPHOID EXCRETORS, INCLUDING A CLINICAL TRIAL IN CONVALESCENCE. (E.) Russell, E. M. (City Hosp., Aberdeen, Scotland), A. Sutherland and W. Walker. Brit. Med. J. 2(5513):555-557, 1966.
In 114 early convalescent typhoid excretors, a double-blind clinical trial of ampicillin (4 g/day for 10 days in adult) and inert capsules was made to assess the efficacy of this drug in preventing the chronic carrier state. Of these patients, 29 were withdrawn for various reasons. Of the remaining 85, 10 of 45 in the treated group and 18 of 40 in the control group excreted Salmonella typhi afterwards; this was of borderline significance ($P < 0.05$). Of the 52 persistent excretors who completed 3 mo. of treatment (3 g/day), 3 excreted S. typhi thereafter and became chronic carriers; 2 of these patients received a further 3-mo. course of ampicillin with probenecid, without effect. In 3 other persistent excretors intolerant to ampicillin, a number of antibiotics (including cephaloridine) were not effective. The mode of action of ampicillin and possible limitations in its use are discussed.
- 1036 THE PATHOGENESIS OF "CLAY-PIPE STEM CIRRHOSIS" IN MICE WITH CHRONIC SCHISTOSOMIASIS MANSONI, WITH A NOTE ON THE LONGEVITY OF THE SCHISTOSOMES. (E.) Warren, K. S. (Western Reserve U. Sch. Med., Cleveland, Ohio). Am. J. Path. 49(3):477-489, 1966.
Swiss albino female mice (100) were exposed to 35 cercariae of a Puerto Rican strain of Schistosoma mansoni and the worm burden 8-52 wk. after exposure was determined in 45 animals by perfusion of their portal and mesenteric vessels. The degree of infection remained constant (av. 7-8 worms/mouse) during the entire study. Mortality was low, but hepatosplenomegaly, portal hypertension, and esophageal varices occurred within 16 wk. At 8 wk. after exposure to S. mansoni, liver wt. (as percentage of body wt.) was 42% less than that of control uninfected animals. Within 8 wk. after infection, the av. liver burden was over 5,000 schistosome eggs; peak liver egg content was reached at 24 wk. and fell thereafter. Liver sections showed scattered granulomas at 8 wk., followed by linear strand formation at 16 wk., and coalescence into fibrotic bands at 24 wk. and later. Although the av. vol. of collagen around individual eggs continued to decrease after reaching its peak at 8 wk., the highest total liver collagen levels were observed at 52 wk. It is concluded that "clay-pipe stem" cirrhosis results from formation of fibrotic bands derived from residual collagen originating about granulomas, and that schistosomes survive for at least 1 yr. in mice.
- 1037 KANAMYCIN AS AN INTESTINAL ANTISEPTIC AND IN THE TREATMENT OF PERITONITIS: RESUME OF CLINICAL EXPERIENCE. (E.) Cohn, I., Jr. (Louisiana State U. Sch. Med., New Orleans). Ann. N. Y. Acad. Sci. 132(2):860-869, 1966.
Several series of experiments using kanamycin as an intestinal antiseptic were undertaken. In dogs with peritonitis induced by ligation of the appendix and dividing its blood supply treatment with kanamycin (3.0 g i.p.) resulted in a 28% mortality rate in 29 treated dogs, compared to 68% in 28 untreated controls. When kanamycin admin. was delayed for 24 hr. after induction of peritonitis, the mortality rate fell from 80% among 15 controls to 45% among 22 dogs receiving i.m.

GENERAL

kanamycin, and to 13% in 23 dogs receiving repeated i.p. inj. In a preliminary clinical trial with 360 surgical cases (including premature and newborn infants) treated with i.p. kanamycin, there were no complications in 65% of the cases; wound infection was seen in only 17%, and none of the 40 deaths (11%) could be attributed to kanamycin. Current comparative studies with single and multiple i.p. inj. of kanamycin in peritonitis indicated that repetitive therapy was the superior form of treatment. In 50 patients receiving kanamycin preoperatively the only side effects were 3 minor episodes of diarrhea in 3 cases (an incidence of under 0.06%). It is concluded that kanamycin is a valuable drug in preparation of patients for large intestinal surgery and as an adjuvant in the surgical treatment of some complications of colon disease.

- 11038 Salmonella GASTROENTERITIS IN RHESUS MONKEYS. (E.) Kent, T. H. (Walter Reed Army Inst. Res., Washington, D. C.), S. B. Formal and E. H. Labrec. Arch. Path. (Chicago) 82(3):272-279, 1966.

Ten rhesus monkeys (Macaca mulatta) given Salmonella typhimurium strain W118 (3×10^{10} cells intragastrically) developed acute gastroenteritis, the most severe and extensive lesions in the colon. Histologically, the enteritis appeared non-specific except that specifically fluorescing S. typhimurium was demonstrated in the lesions. Colitis was present by 24 hr. after challenge, and subacute inflammation was present at 7 days in 2 of 3 animals. The ileum had an early mild inflammation; a more severe lesion was present at 4 and 7 days. Focal lesions were present in the stomach and jejunum. Fluorescent antibody and cultural techniques demonstrated salmonellae in the colon and ileum up to 4 days after challenge. One animal died; in contrast to the other animals, this monkey had a predominantly histiocytic reaction in the intestines and regional lymph nodes, and more organisms in the lesions.

- 11039 THE INCIDENCE OF OBTURATOR HERNIA IN A 10-YEAR MATERIAL (1955-64), AND ITS IMPORTANCE IN THE OCCURRENCE OF ILEUS. (Hun.) Pakozdy, P. (Szolnok District Hosp., Hungary). Orv. Hetil. 107(34):1609-1611, 1966.

The analyzed surgical material (16,949 cases) included 4389 hernia operations; 221 of these were incarcerated hernias, including 8 obturator hernias (3.62%). The symptomatology and surgical procedure employed in these 8 cases is described. In 72 of the 4389 cases, the nature of the ileus could be diagnosed only during surgery (all patients over 50 yr. of age; 39 cases of small intestinal closure, 33 cases of tumor-induced obstruction); obturator hernias represented 11.1% of this group. It is suggested that in all cases of ileus of obscure etiology, the possibility of obturation or hernia should be considered.

- 11040 ENTEROPATHY IN MALIGNANT DISEASE. (E.) Dymock, I. W. (U. Glasgow, Scotland). Brit. J. Cancer 20(2):236-238, 1966.

Fat excretion (measured as stearic acid) was studied in 14 patients (on a normal diet) with malignant disease of various origins; none had received abdominal radiotherapy, but 4 had received cytotoxic agents. In 6 cases, av. fat excretion exceeded 5 g/24 hr.; in 5 of these cases, the range of fat excretion was 5.5-10.2 g/24 hr. (av. over 6 g/24 hr.). None of these patients had overt steatorrhea, however. Jejunal biopsies, obtained from 3 of these patients, showed partial villous atrophy in 2 and blunting of the villi in the other. The xylose absorption test was abnormal in all 6 cases; 5 patients showed abnormal urocanic and formiminoglutamic acid excretion. Hemoglobin levels were 12 g or less in 7 of the 14 patients; 3 of these patients also showed macrocytosis, and 2 of these 3 patients also showed fecal fat excretion over 6 g/24 hr. The patients with elevated fat excretion levels (over 6 g/24 hr.) did not have reticulosis or tumors involving the intestine; autopsy examination of 3 patients who later died showed no signs of malignant involvement of the small intestine or the mesenteric lymph nodes.

- 11041 CIRCUMOVAL PRECIPITIN TEST IN Schistosomiasis mansoni. A STUDY OF 400 PATIENTS. (E.) Rodriguez-Molina, R. (VA Hosp., San Juan, Puerto Rico), J. Oliver-Gonzalez and A. Rivera de Sala. Bol. Asoc. Med. P. Rico 58(4):159-165, 1966.

GENERAL

Stool examinations and rectal biopsies were performed in 400 patients with confirmed Schistosoma mansoni infection, 100 subjects from an endemic area who had been treated with antiparasitic agents (Stibophen, Fuadin R), and 100 subjects apparently free of schistosomiasis. Sera from patients with positive biopsy and/or stool examinations were added to ova isolated from the livers of mice infected with S. mansoni 10 wk. previously. The precipitin test is described in detail. The strength of the reaction was determined by the number of ova showing the circumoval changes (hyaline, finger-like, sometimes septate projections) after treatment with the sera. Positive reactions were seen in the sera of 92% (368) of the 400 patients with confirmed schistosomiasis; only 11% of previously treated patients had negative precipitin reactions, although stool examination was negative in 45.7%. All subjects in the third group (apparently free of disease) had negative precipitin tests.

- 1042 Salmonella anatum: REPORT OF AN ALASKAN OUTBREAK. (E.) Butler, C. E. (Aerospace Med. Div., Air Force Systems Command, Fort Wainwright, Alaska), W. L. Miller and C. T. Marrow. Arctic Aeromedical Lab. (AAL-TR-66-5): 1966.

Residents of central Alaska experience an outbreak of mild, afebrile gastroenteritis during the warm weather each yr. The cause is undetermined, possibly a virus. A sudden outbreak of similar gastroenteritis during the autumn of 1964 among 25-30 students at the University of Alaska is described. Examination of the students with mild or (4 cases) severe, febrile symptoms, and bacteriological screening of a total of 300 students and other University personnel, resulted in the isolation of Salmonella anatum from 43 individuals. The outbreak may have resulted from contamination of food by 2 asymptomatic food handlers. All but 2 of the positive subjects were treated with antibiotics, including neomycin, tetracycline, chloramphenicol, paromomycin, and ampicillin in 2- or 3-drug combinations. This treatment rapidly reduced the symptoms, but not all agents had equal antibacterial effect; the most effective seemed to be ampicillin. Sensitivity tests were made.

- 1043 HUMAN ENTERIC PATHOGENS IN DOGS IN CENTRAL ALASKA: II. (E.) (Butler, C. E. (Arctic Aeromed. Lab., Fort Wainwright, Alaska) and C. E. Busbee. Arctic Aeromedical Lab. (AAL-TR-66-4): 1966.

A second-yr. survey (1965) of Salmonella and related enteric pathogens in dogs in Fairbanks, Alaska, showed that house dogs within the city have a higher incidence of these bacterial species than groups of dogs in other localities in Central Alaska. In the present survey, of 192 samples collected from 132 dogs, 9 different species of Salmonella were recovered (give, senftenberg, minnesota, worthington, ferro, montevideo, siegburg, lexington, and urbana), bringing the number of species of Salmonella up to 20 for the 2-yr. period. Related species of the family Enterobacteriaceae (excluding Escherichia coli) were Bethesda-Ballerup, Arizona, alkalescens-Dispar, and Hafnia. No relationship between the species found in dogs and those recovered from human cases could be established. The transitory and sequential nature of the bacterial populations seen in some dogs at least was studied. One dog showed no pathogens on Feb. 15, 1965; from the same dog S. ferro was isolated on Feb. 15, 1965; in July S. lexington was recovered. From another dog on the same dates, the sequence of recovery was S. senftenberg, S. minnesota, and S. senftenberg. S. worthington was recovered in pure culture from a pet city dog which was free of any symptoms of disease. Very few dogs displayed any signs of disease; when symptoms did (rarely) occur, they were very similar to those produced in humans.

- 1044 THE TREATMENT OF MASSIVE GASTRO-DUODENAL HEMORRHAGES (EXCLUDING PORTAL HYPERTENSION). (Fr.) Sicard, A. and G. Lavarde. Mem. Acad. Chir. (Paris) 92(18-19):523-529, 1966.

Massive gastroduodenal hemorrhages were characterized by large decreases in the Hb and serious lesions or hematemesis. Of 70 patients observed for serious hematemesis or melena, 50 underwent surgery. The lesions observed were 25 gastric ulcers (in patients over 40 yr.), 20 duodenal ulcers, 2 peptic ulcers, 1 massive hemorrhage due to a schwannoma, and 2 cases of unknown etiology. Preoperative

GENERAL

interrogation showed most patients to be aware of some ulcerous conditions; only 2 had been in previously good health when the attack came. Radiological examination also indicated 7 gastric ulcers, 1 duodenal ulcer, and 1 schwannoma of the stomach. Gastrectomy (Pean or Finsterer type) was performed in 30 patients with persistent bleeding, including 8 with recurrent bleeding after quick-freezing treatment. Seven of the patients with persistent bleeding died following gastrectomy but only 1 of the 8 patients gastrectomized for recurrent bleeding. The other patients were initially treated by reanimation, but were subject to recurring hemorrhages; 11 were later gastrectomized. Severe hemorrhagic ulcers were found in patients with cerebral lesions. The quick homeostasis following blood transfusion is a favorable element for surgical treatment, but extended transfusions given over long periods of time to reach equilibrium appear to be a negative factor for later surgery.

- 11045 GASTRIC STUDIES IN SJÖGREN'S SYNDROME. (E.) Buchanan, W. W. (Western Infirm., Glasgow, Scotland), A. G. Cox, R. M. Harden, A. I. M. Glen, J. R. Anderson and K. G. Gray. *Gut* 7(4):351-354, 1966.

When tests for gastric parietal cell antibodies, augmented histamine tests and gastric mucosal biopsies were conducted on 6 women (ages 56-73 yr.) with Sjögren's syndrome, 4 were found to have no acid in the basal and histamine-stimulated gastric juice. Furthermore, in 3 of these 4 the vol. of gastric secretion was very low, antibodies to parietal cells were demonstrated and the mucosal biopsy showed severe gastritis (with metaplasia to intestinal type of gland in one). Although the fourth of these patients was achlorhydric, the vol. of secretion was moderately large, the test for parietal cell antibodies was negative and the histology failed to reveal gastritis. It is significant that in these 4 patients, the xerostomia was more severe and the sicca component of longer duration than in the remaining 2 who had an acid gastric juice. However, both patients showed gastritis, but parietal cell antibodies were absent. Although the number of patients studied is relatively small, the frequency of gastric abnormalities is striking and suggests that gastric malfunction might be a component of Sjögren's syndrome.

- 11046 ABDOMINAL COMPLICATIONS OF Ascaris lumbricoides INFESTATION IN CHILDREN. (E.) Louw, J. H. (U. Cape Town, South Africa). *Brit. J. Surg.* 53(6): 510-521, 1966.

Of 731 acute abdominal emergencies in children between the ages of 1 and 12 yr., 12.8% were due to Ascaris lumbricoides in a children's hospital in Cape Town, South Africa. This percentage rated second only to appendicitis. In total, Ascaris accounted for 37.5% of all the deaths in this group, rating second only to the number caused by primary peritonitis. Of these 100 children with Ascaris, 68 had intestinal obstruction, 17 had biliary lesions, 11 had pancreatitis, 2 had appendicitis and 2 had primary peritonitis due to the Ascaris. Intestinal obstruction was the most common complication (the disease accounted for 25% of the hospital admissions for intestinal obstruction) and in most cases the obstruction was incomplete and responded to conservative treatment. However, 16% of the cases required emergency surgical treatment due to complete occlusion or strangulation from intraluminal blockage, intussusception, volvulus or associated bands. In 2 cases the worms per se caused necrosis of the intestinal wall. In those cases of biliary obstruction, 50% presented hepatic enlargement and 20% presented jaundice. Usually conservative treatment sufficed, but where i.v. cholangiography showed a persistent shadow in the common duct, surgery for the removal of the worms was necessary. In 25% of the cases of acute pancreatitis, there was also evidence of associated biliary obstruction. Here again, conservative treatment usually was indicated except when enormous pseudocysts or granulomata with biliary obstruction were present.

- 11047 DIFFUSE GASTROINTESTINAL POLYPOSIS WITH ECTODERMAL CHANGES. (E.) Manousos, O. (Radcliffe Infirm., Oxford, England) and C. U. Webster. *Gut* 7(4):375-379, 1966.

In a 61-yr.-old man with acute diarrhea, weakness, and severe wt. loss, diffuse gastrointestinal polyposis was diagnosed by X-ray examination, which showed masses

of polyps in the gastric fundus area, small defects in the small intestine, and small sessile polyps in the ascending colon. There was no family history of digestive diseases. Nails were thick, white and brittle, and pigment changes were noted in the palmar creases, forearms and back, and a few areas of alopecia were noted. Hypokalemic alkalosis and low serum calcium and magnesium values were also seen; fecal electrolyte loss was excessive and was accompanied by a 10 mEq/kg urine loss every 24 hr. During surgery (75% Polya gastrectomy) to remove the vast secretory mass in the stomach, a few large tumors were noted in the duodenal mucosa and treated by diathermy. Replacement therapy was also given. The patient improved markedly over the next 11 mo. until the time of report. Histologically, edematous polyps and elongated, cystic gastric pits were observed in the mucosa. The 3 other reported cases of this syndrome are compared to this one; it is concluded that the features described result from varying degrees of deficiency of electrolytes, albumins, minerals, and amino acids. The similarity in deficiencies to chronic hypoparathyroidism is emphasized.

- 1048 SERUM MAGNESIUM LEVELS IN ACUTE GASTROENTERITIS IN CHILDHOOD. (E.) Paul, F. M. (U. Singapore) and D. O'Brien. Singapore Med. J. 7(2): 98-104, 1966.

A total of 83 children, aged from 1 mo. to 7 yr., patients in hospital suffering from severe gastroenteritis, had blood samples taken. The blood samples were centrifuged and the serum refrigerated prior to analysis for Na and K by flame photometry, for Cl electrometrically, for Mg and Ca fluorometrically. Blood samples from 18 healthy normal children of the same age and ethnic distribution were also analyzed to provide control data. The mean Mg level in the cases of gastroenteritis was significantly below that of the normal; 39 of 83 cases had serum Mg levels more than 2 standard deviations below the normal mean. Despite the high incidence of hypomagnesemia, there was no apparent correlation between Mg levels and Na or K levels. There was a highly significant positive correlation between serum Ca and Mg levels. It was also apparent that neither the severity of the disease nor its outcome could be predicted on the serum Mg level. However, these findings justify the addition of Mg to polyelectrolyte resuscitating soln. and is recommended for the management of gastroenteritis.

- 1049 THE NEGLECTED AMEBA: Dientamoeba fragilis. A REPORT OF 100 "PURE" INFECTIONS. (E.) Kean, B. H. (Cornell U. Med. Coll., New York, N. Y.) and C. L. Malloch. Am. J. Dig. Dis. 11(9):735-746, 1966.

A review is presented of 100 cases of Dientamoeba fragilis encountered during the years 1957-1964 by the Tropical Medical Unit, Cornell Medical College; these were all the cases with stool specimens positive for at least 1 parasite. These 100 cases were found among 14,203 patients and were "pure" cases, having no other protozoan parasites. Examination included direct saline smears, use of Lugol's soln., culture, and staining. Specimens were successfully cultured in 85 cases. There are a large number of questions concerning the life cycle and structural details (especially nuclear) that are still unanswered; these are enumerated and discussed. The most frequent presenting symptoms by patients were abdominal pain, diarrhea, flatus, nausea, vomiting and fatigue. Physical signs, proctoscopic examination and radiologic study usually were negative. Treatment with Carbarsone (250 mg 2-4 times daily) or tetracycline (4 cases) for 7-10 days eliminated the parasite, although evaluation of symptomatic relief was often difficult. D. fragilis is considered by many to be nonpathogenic and is often ignored. This appears unjustified in view of the cases reviewed. Specific therapy seems warranted.

- 1050 Salmonella GASTROENTERITIS IN RHESUS MONKEYS. (E.) Kent, T. H. (Walter Reed Army Inst. Res., Washington, D. C.), S. B. Formal and E. H. Labrec. Arch. Path. (Chicago) 82(3):272-279, 1966.

Ten rhesus monkeys (2-3 kg body wt.) housed in individual cages with ample food and water were given 3×10^{10} living organisms (Salmonella typhimurium) in 20 ml broth by gastric intubation. Two monkeys each were killed at 1, 2, and 4 days postchallenge and 3 were killed at 7 days; the tenth animal was found dead at day 4. Some tissues were fixed and prepared for histologic examination, and some tissues

GENERAL

were frozen. Specimens were obtained from all regions of the gastrointestinal tract and from other organs. Sections of the frozen tissues were used for fluorescent antibody studies after treatment with fluorescein-labeled rabbit antiserum of *S. typhimurium*. The animals developed an acute gastroenteritis with the entire colon showing the severest and most extensive lesions of the entire gut. The colitis was present 24 hr. after challenge and subacute inflammation was still present at 7 days in 2 of 3 animals. The ileum had an early mild inflammatory reaction and a more severe lesion was present at 4 and 7 days. Focal lesions were also present in the stomach and jejunum. The fluorescent antibody technic revealed that salmonellae were present in the ileum and colon up to 4 days after challenge. Relatively few bacteria were found in the gut compared to the numbers found in shigellosis. The numbers of salmonellae encountered hardly seemed to account for the extent and severity of lesions.

- 11051 EVALUATION OF OUR EXPERIENCE WITH LAPAROSCOPY. (Sp.) Ocariz E., J. H. (Los Andes Hosp., Merida, Venezuela). G.E.N. 20(3):601-608, 1966.

Laparoscopy was performed as an adjunct to X-ray and clinical diagnostic studies in a total of 212 patients, aged 5-91 yr., with diagnostic findings confirmed in 192 of 212: in 47 cases, by biopsy; in 43, at surgical intervention; in 11, at autopsy; in 5, by cytologic studies of ascitic fluid and in 86, by further clinical studies during subsequent progress of the disease. The technic was unsuccessful in 5 of 212, and 15 of 212 were lost to follow-up. Failures were due in 3 cases to extensive adhesions, which prevented visualization of the liver; in 1 case, to inadequate pneumoperitoneum; in 1 case, to stopping with discovery of a massive abscess of the abdominal wall, without continuing on into the abdominal cavity. Accidents were limited to 2 cases of damage to the liver and 1 case of inadvertent lesion of a vein in the abdominal wall which was discovered at autopsy.

- 11052 CONGENITAL TUMORS OF THE PAROTID GLAND. (E.) Vawter, G. F. (Children's Hosp. Med. Ctr., Boston, Mass.) and M. Tefft. Arch. Path. (Chicago) 82(3):242-245, 1966.

Congenital tumors of the parotid gland were diagnosed at birth in 2 infants (1 boy, 1 girl). The girl was treated by radical surgery, radiotherapy (2600 r over 29 days) and courses of 5-fluorouracil and vinblastine (doses not stated) and was free of recurrence 3 yr. later; postoperative complications included partial facial palsy and some feeding difficulties. The boy was treated with surgery and radiotherapy (2200 r over 14 days); partial facial palsy was seen thereafter. A local recurrence in the scar was excised at age 6 mo. and a second recurrence was excised at age 10 mo. No extension to the ipsilateral cervical lymph nodes was noted. The child remained free of tumor thereafter; at the age of 12 yr. he had compensated for the facial palsy so well that he did not wish reconstructive surgery. Both excised tumors were similar in gross and microscopic appearance. They were obviously of parotid origin and consisted predominantly of a serous epithelial cell without a nonspecific esterase reaction. A mixed tumor pattern was seen in the boy. These tumors were described as "embryomas", not teratomas, with a local malignant potential indicated by repeated local recurrences and areas of high mitotic activity.

- 11053 STUDIES ON URINARY VANILMANDELIC ACID IN THE PATIENTS WITH DIGESTIVE, BRAIN AND NERVOUS DISEASES. (Jap.) Nakano, Y. (Kyoto U. Sch. Med., Japan), T. Esaki, Y. Sugano, S. Shinbo, Y. Nagayama and Y. Ishii. Naika Hokan (Jap. Arch. Intern. Med.) 12(12):707-714, 1965.

In patients with digestive, brain and nervous disorders, the urinary excretion of vanilmandelic acid (VMA) was determined daily and its relationship to catecholamines (CA) and total metanephrine (MN), in the same urine sample, was assessed. Daily urinary VMA was increased in acute hepatitis, decreased in chronic hepatitis, and normal in liver cirrhosis. In all of the diseases, especially chronic hepatitis and cirrhosis, the CA:VMA and MN:VMA ratios increased. Accompanying any deleterious change, VMA increased in acute hepatitis and decreased in cirrhosis; the CA:VMA and MN:VMA ratios increased in both cases, and returned to normal upon recovery. There was no significant correlation between VMA and sulfobromophthalein retention,

GENERAL

serum transaminases, or serum cholesterol values in these patients. These data suggested a decrease in monoamine oxidase activity in these liver disorders. VMA excretion was increased in liver and stomach cancer, normal in obstructive jaundice and decreased in gastric and duodenal ulcer; it was decreased in most patients with brain tumors, and the CA:VMA and MN:VMA ratios were higher than those of healthy subjects, but there was no significant correlation with the type or location of the tumor or the cerebrospinal fluid pressure. VMA excretion was increased in patients with amyotrophic lateral sclerosis and paralysis agitans; it decreased slightly in neurofibromatosis, and in progressive paralysis it increased in 4-8 hr. VMA excretion was normal in cases of simple obesity, aplastic anemia and abnormal pigmentation, and increased in patients with lung sarcoma and acute myeloid leukemia.

- 11054 EXPERIMENTAL STUDIES ON THE PREVENTION OF THE INTESTINAL ADHESION. (Jap.) Sakakihara, Y. (Tokushima U. Sch. Med., Tokushima, Japan). Shikoku Igaku Zasshi (Shikoku Acta Med.) 22(3):473-485, 1966.

The ileocecum of rabbits was subjected to bacterial infection and mechanical manipulation. The incidence of adhesion, classified by the degree of intestinal injury, was: Grade 1 injury (slight scratching) = 60%; Grade 2 injury (strong scratching) = 80%; Grade 3 injury (serosal scraping) = 100%; and Grade 4 injury (serosal scraping and bacterial infection) = 100%. When chemical injury and mechanical manipulation were combined, the incidence was 100% for Grade 2 injury with 3% tincture of iodine, and 100% for Grade 3 injury with 3% tincture of iodine. On examination of the relationship between degree of injury and the agent introduced, inhibition of adhesions by the agent was recognized in groups of Grade 1 and 2 injuries, but there was no significant inhibition in cases of Grade 3 and 4 injuries. Physical and chemical properties of an individual agent did not appear specifically to prevent peritoneal adhesion. Adhesions were infrequent in animals in which the agent remained in the peritoneal cavity for a long time. Connective tissue formation in the injured intestinal wall, examined biochemically by determining glucosamine and hydroxyproline content, resembled the process of wound healing proposed by Dunphy and Udupa; the mucopolysaccharides in the ground substance played a significant part in the formation of connective tissue and collagen.

- 11055 ON THE PREVALENCE AND INCIDENCE OF CARCINOIDS IN MALMÖ. (E.) Linell, F. (U. Malmö, Sweden) and K. Mansson. Acta Med. Scand. 179(Suppl. 445): 377-382, 1966.

The prevalence of carcinoids was studied in a representative 4-yr. autopsy series (1959-1962) from Malmö, Sweden (population 230,000), where about 60% of all people dying are autopsied at the hospital. The prevalence of gastrointestinal tract carcinoid tumors was 1.1% (53 of 4828 autopsies); for bronchial carcinoid it was 0.1% (5 of 4828). Most (43) of the 53 carcinoids were found in the small intestine, none in the appendix. In 25% (13) of the cases they were multiple; 25% of the patients had metastases. There were fewer cases (2) with metastases among the multiple carcinoids; in 4 cases, carcinoids were the direct cause of death. The incidence of carcinoids was studied in a 6-yr. series (1957-1962) of patients operated upon at Malmö General Hospital. The incidence of gastrointestinal tract carcinoid was less than 1/100,000/yr.; most were carcinoids of the appendix and were more common in males. The incidence of bronchial carcinoid was slightly less than 50% of this figure. The very rare carcinoid syndrome was noted in a case of ovarian teratoma with carcinoid structures.

ESOPHAGUS

- 11148 EMERGENCY TREATMENT OF BLEEDING ESOPHAGEAL VARICES IN CIRRHOSIS. (E.) Orloff, M. J. Curr. Probl. Surg. 1966:13-28.

Emergency diagnostic procedures consisting of a medical history and physical examination for signs of cirrhosis, blood studies with liver function tests (sulfobromophthalein retention and prothrombin time are especially valuable), and X-ray examination (which demonstrates esophageal varices in 95% of cases), were sufficient to diagnose bleeding esophageal varices due to cirrhosis in 90% of cases of hemorrhage from the upper gastrointestinal tract. Such tests can be carried out within 2-4 hr of admission. Other diagnostic tests in doubtful cases include splenic manometry, esophagoscopy (only if bleeding is not massive), balloon tamponade, and splenoportography. Emergency treatment consists of restoration of blood vol., electrolyte balance, and blood ammonia levels. Medical treatment of bleeding varices consists of balloon tamponade, admin. of posterior pituitary extract, and gastroesophageal hypothermia. Portacaval shunt is more reliable than transesophageal ligation of varices as a specific surgical measure. The necessity for accurate early diagnosis and adequate treatment is stressed, because of the high hospital mortality rate (67%) in patients with cirrhosis and bleeding varices.

- 11149 THE WATER TEST IN THE EVALUATION OF GASTROESOPHAGEAL REFLUX. ITS CORRELATION WITH PYROSIS. (E.) Crummy, A. B. (U. Wisconsin Med. Ctr., Madison). Radiology 87(3):501-504, 1966.

An analysis of the findings in 650 patients formed the basis of this report on the use of the water test for inducing gastrointestinal reflux in susceptible subjects. During routine examination when the patient was supine, he was turned into the right posterior oblique position in relation to the fluoroscopic table so that the region of the cardioesophageal junction filled with barium. The patient was then asked to take a mouthful of water through a straw (15-30 ml). While the gastroesophageal junction was observed fluoroscopically the patient was asked to swallow. Usually sufficient air was ingested with the water so that the bolus of water could be identified in the esophagus and as it entered the stomach its presence could be detected before it mixed in the barium. Normally there was no barium reflux into the esophagus; occasionally a minute amount flowed back for 1-2 cm, but it was immediately cleared into the stomach. This was a negative test. The test was positive when there was an abrupt eruption of barium into the esophagus, usually to the level of the pulmonary hilus and frequently above the aortic arch; the clearing of the esophagus was slow and several peristaltic waves might pass before the region was cleared. Review of the data showed that in 67 patients (10.3%) reflux was provoked by the water test and 46 of these (68.6%) complained of pyrosis. Conversely 583 (89.7%) did not have reflux when tested with water and only 20 (3.4%) complained of pyrosis. Hiatal hernia was found in 46 subjects; 22 of these had pyrosis and in 20 (91%) the water test was positive; of the 24 asymptomatic patients with hiatal hernia, the water test was positive in 2. In 39 (86%) of 46 patients the demonstration of reflux was by the water test only.

- 11150 ACHALASIA OF THE CARDIA IN INFANCY AND EARLY CHILDHOOD. (Ger.) Yanagisawa F. (U. Hamburg, Germany). Zschr. Kinderchir. 3(3):344-354, 1966.

Observations in 20 patients treated for esophageal achalasia between ages 1-14 yr. indicated that two types of the disease exist: the clinically more severe achalasia of Infancy, with symptoms starting before age 2 (14 of 20 cases), and the milder "adult" form whose symptoms appear in early puberty (6 of 20) and resemble those seen in adult patients. In 4 patients of the former group, surgery revealed cartilaginous inclusions in the wall of the lower esophagus, presumably derived from mesenchymal cells displaced during formation of the upper respiratory tract. Depending on the size of the inclusions, the clinical symptomatology may be that of achalasia or of congenital stenosis of the esophagus.

- 11151 REASSESSMENT OF THE FATE OF ESOPHAGEAL VARICES FOLLOWING PORTAL DECOMPRESSION IN CIRRHOSIS. (E.) Palmer, E. D. (VA Hosp., East Orange, N. J.). Am. J. Gastroent. 46(1):38-42, 1966.

ESOPHAGUS

post-shunt esophagoscopy evaluations (420 total) conducted on 132 cirrhotic patients who had survived surgical portal decompression as a treatment for esophageal varices illustrated that a splenorenal shunt (SR: 23 cases) was less effective than a portacaval shunt (PC: 109 cases) in eradicating varices, both in immediate and long-term effect. At the time of the final esophagoscopy evaluation of each patient, varices were present in 27% of the PC patients and 78% of the SR patients. These evaluations were conducted over a period of 1 mo.-10 yr. Among the PC patients, the early esophagoscopy examinations showed varices more often than did the later ones: during the first 2 postoperative mo. varices were found in 46% of the cases, whereas in 4 mo. varices were found in only 19%. No such tendency was observed among the SR patients. In only 6 patients did the varices recur after having disappeared: 2 in the SR group and 4 in the PC group. In none of these patients did the varices spontaneously disappear again, but no bleeding occurred from these varices so that a second decompression operation was not considered necessary. At autopsy in 4 cases, it was seen that the shunt was well formed and patent.

1152 SLIDING HIATUS HERNIAS IN IDENTICAL TWINS. (E.) Sidd, J. J. (Vet. Admin. Hosp., West Roxbury, Mass.), J. I. Gilliam and B. P. Bushueff. Brit. J. Radiol. 39(465):703-704, 1966.

A 43-yr.-old man hospitalized for exertional retrosternal chest pain was diagnosed as coronary artery disease and a sliding hiatus hernia. Three siblings, including the patient's identical twin and 2 other brothers, showed moderately sized sliding hiatus hernias of the same size and X-ray configuration at age 42-44 yr. The twins had symptoms, the others did not. This is the first report of this acquired type of hiatus hernia in identical twins or a sibling group. None of the suggested causative agents (such as obesity, ascites, prolonged cough, or a broad, flaring chest configuration) were present in these brothers, but the presence of the condition in monozygotic twins strongly suggests the importance of genetic influences, at least in this family.

1153 THE MALLORY-WEISS SYNDROME AND LESION. A STUDY OF 30 CASES. (E.) Dagradi, A. E. (VA Hosp., Long Beach, Cal.), J. T. Broderick, G. Juler, S. Wolinsky and S. J. Stempien. Am. J. Dig. Dis. 11(9):710-721, 1966.

All 30 patients in this study ranged in age from 31-64 yr., 71% in the 30-49-yr. group; 24 were alcoholics. In 22 cases bleeding ceased spontaneously with supportive medical management. Surgical intervention was required in 8; 2 patients died, 1 because of pulmonary embolism, the other from recurrent gastrointestinal hemorrhage due to congestive hemorrhagic gastritis. In 18 patients, severe paroxysmal coughing, non-bloody emesis or retching preceded the hematemesis. An esophageal hiatus sliding hernia was found in all patients. Diagnosis was by esophagoscopy alone in 9, by gastroscopy alone in 12, by both methods in 8 and by surgical exploration in 1. Diagnosis by X-ray was also accomplished in 20 and at prior or subsequent admissions in 5 others. The lesions were longitudinal tears, usually single (28 cases), in the upper cardia, never involving the esophagus. Acute increased intraabdominal pressure and the presence of an esophageal hiatus sliding hernia seem to be necessary for the production of the Mallory-Weiss lesion. Therapy involves blood replacement, control of bleeding, and promotion of healing. Oral admin. of a thrombin-Gelfoam mixture to aid coagulation and antacids to depress peptic activity assist healing. Nasogastric tubes may dislodge clots, and balloon tamponade may distend the laceration.

1154 ESOPHAGEAL MOTILITY IN TRACHEOESOPHAGEAL FISTULA AND ESOPHAGEAL ATRESIA. (E.) Lind, J. F. (Winnipeg Gen. Hosp., Winnipeg, Manitoba, Canada), R. J. Blanchard and H. Guyda. Surg. Gynec. Obstet. 123(3):557-564, 1966.

In 10 children, aged 2-11 yr., who had undergone repair of esophageal atresia and tracheoesophageal fistula within the first 4 days of life, were studied by manometric techniques, and the results obtained compared to those from 10 normal children of similar age. Pressure tracings were obtained in the stomach, sphincter and esophagus; simultaneous respiratory records were also taken. The pressure (in mm H₂O) was measured by strain gauges connected to amplifiers and recorder. During deglutition there was no relaxation of the gastroesophageal sphincter in 7 of the experimental group; in 3 the results were inconclusive; all 10 control children showed definite relaxation of this sphincter during deglutition. Following deglutition

ESOPHAGUS

contraction of the gastroesophageal sphincter occurred in all children, experimental and control. In some experimental subjects contraction of the sphincter was prolonged. In the body of the esophagus all children of the experimental group had feeble, simultaneous and repetitive contractions involving the entire esophagus. There was no peristaltic activity. In the control group all showed normal peristaltic waves, adequate in amplitude and rate of conduction. The experimental subjects displayed motility patterns for the esophagus indistinguishable from those seen in achalasia. This phenomenon serves to explain dysphagia in the absence of any endoscopic or X-ray evidence of esophageal stricture.

- 11155 "INVAGINATION" OF THE ESOPHAGUS INTO THE STOMACH IN HIATUS HERNIAS. (Rus.) Aizenshtat, A. I. (Union Hosp. #3, Minist. Pub. Health Latvian SSR, Riga). Med. Klin. 44(6):58-62, 1966.

A supradiaphragmatic ring or "collar" appeared upon X-ray examination of the esophagogastric junction in 12 of 271 patients with hiatus hernia. The mechanism of appearance of this sign indicated a specific form of hiatus hernia ("collar-like" form) rather than esophageal invagination into the stomach. Elaborate X-ray examination of the esophagogastric area showed that formation of such a "collar" is not a rarity. This type of hiatus hernia was sometimes accompanied by vomiting and its clinical sequelae, but was not itself an additional indication for surgery. None of the 12 patients with "collar-like" hiatus hernia had symptoms of dysphagia.

- 11156 DIAGNOSTIC AND THERAPEUTIC RESULTS OF SLIDING DIAPHRAGMATIC HERNIA. (E.) Sottile, V. M. (Staten Island Hosp., N. Y.). Am. J. Gastroent. 46(4):317-327, 1966.

A series of 20 adults (11 female, 9 male; age 27-78 yr.) with symptomatic sliding diaphragmatic hernia, who had been unsuccessfully treated medically, was evaluated by X-ray and esophagoscopy, then treated by surgical repair of the hernia with pyloroplasty and vagotomy. Retrosternal burning was the presenting symptom in all cases. In no cases were there X-ray evidence of esophagitis, and 4 patients (20%) failed to demonstrate a hernia on X-ray. A sliding diaphragmatic hernia was visualized by esophagoscopy in 100% of the cases; this also demonstrated some degree of superficial esophagitis in all cases. After surgery, 19 of 20 patients (95%) were cured of their symptoms; 95% also thought that the operation was worthwhile. Post-vagotomy symptoms were mild in 30% and moderate in 40%. It is suggested that addition of vagotomy and pyloroplasty offers definite therapeutic advantages over simple repair of diaphragmatic hernia.

STOMACH

(Gastric ulcer is placed with peptic ulcer)

- 11179 VARIATIONS OF TOTAL BODY POTASSIUM AFTER GASTRIC RESECTION. (It.)
Rossi, R. (U. Milan, Italy), V. Scortecchi and O. Ferri. *Minerva Med.*
57(13):492-496, 1966.

In 10 patients undergoing gastric resection for gastric or duodenal ulcer, total available potassium levels were estimated 3-4 days before surgery and during days 2-7 postoperative, with estimates based on serum levels and urinary excretion levels of radioactivity, 8 hr. after admin. of K^{42} -labeled potassium chloride (3.6 mc/kg, i.v.). In 8 of 10 patients, only very minimal changes were seen, as between conventionally-determined pre- and postoperative serum potassium levels, not exceeding normal-range expectation for day-to-day fluctuation. In the remaining 2 of 10, postoperative levels were very slightly lower than would be consonant with normal fluctuation. However, at 30-36 hr. post surgery, indicated totals of available potassium, estimated as above, were significantly higher than the preoperatively-determined base; then fell slowly, to reach the preoperative baseline by day 4 and move below it progressively during day 5-7. In 2 of 10 patients, losses of approx. 80% the base value for total available potassium were indicated by the end of the observation period, although concurrent, conventional determinations of serum potassium levels failed to reflect this development. It is concluded that serum potassium levels, as such, are highly unreliable as indicators of postoperative gain or loss of the electrolyte and that radioisotopic studies, permitting estimation of total available potassium levels, are absolutely necessary to the successful maintenance of postoperative control in this respect. Individual differences within the patient group were too great to permit drawing any reliable conclusions concerning the rate at which normal potassium equilibrium should be expected to reestablish itself after surgery.

- 11180 STUDIES ON THE SECRETORY ACTIVITIES AND MORPHOLOGICAL STRUCTURE OF THE GASTRIC MUCOSA IN CHRONIC GASTRITIS. (Ger.) Krentz, K. (U. Hosp., Eppendorf, Germany). *Acta Gastroent. Belg.* 29(7):641-666, 1966.

The relationship between secretory activity and morphology of the gastric mucosa was studied in 50 normal subjects and 50 patients with superficial chronic gastritis (25) or atrophic gastritis (25). Values for gastric secretion in normal subjects and patients with superficial and atrophic gastritis were: vol. 74, 69, and 39 ml/hr.; resp.; free HCl 101, 41, and 15 mg/hr., resp.; acid primary secretion 26, 17, and 6 ml/hr., resp.; alkaline primary secretion: 48, 52, 33 ml/hr., resp.; acid:alkaline primary secretion ratio 35:65%, 24:76% and 15.3:84.7%, resp. The Betazole stimulated secretion values were: total vol. 152, 128, and 57 ml, resp.; free HCl 431, 221, and 74 mg/hr., resp.; primary acid component 96, 57, and 16 ml, resp., alkaline component 56, 71, and 41 ml/hr., resp.; acid:alkaline primary ratios 63.1:36.9%, 44.5:55.5%, and 28:72%, resp. Pepsin and cathepsin values (in hemoglobin U x 10^{-3} /ml) were: normal 4.9 and 3.7, resp.; superficial gastritis 3.7 and 2.8; and atrophic gastritis 1.8 and 1.2. Total enzyme secretions (in hemoglobin U/60 min.) were 0.34 and 0.31; 0.29 and 0.20; and 0.13 and 0.07, resp. The av. mucosal layer thicknesses were 0.18, 0.24, and 0.39 mm, resp., for the epithelial layer; 0.62, 0.44, and 0.17 mm, resp., for the glandular layer; and 0.19, 0.16, and 0.28 mm, resp., for the muscularis mucosa. The total thickness of all layers, however, was practically unchanged (0.91, 0.87, and 0.92 mm, resp.).

- 11181 MICROPOLYPOSIS OF THE STOMACH. (Rus.) Khanin, M. G. (Inst. Anat. Surg., Moscow) and D. S. Sarkisov. *Khirurgiia (Moskva)* 42(5):26-29, 1966.

Of 61 patients treated by surgery for gastric polyps, 36 showed multiple (2-50) polyps and 25 had single polyps. In 73% of cases the polyps were located in the caudal part of the stomach. The polyps were glandular in 58 (6 showed transitions into cancer) and fibrous in 3. Atrophic changes in gastric mucous membrane were absent. Micropolyposis was found by histo-topographic examination in 26 of 61 including patients with both multiple and single (12 of 25) polyps. Diffuse hyperplastic changes of the gastric mucous membrane (of the micropolyposis type) were more frequently localized in the prepyloric and pyloric stomach. Gastric resection was preferred to resection of the polyps, alone or together with a part of the gastric wall. From 1948-65, 170 of 248 patients with gastric polyps had surgery. Of 138 patients

TOMACH

undergoing gastric resection or gastrectomy, 58 were followed up; 5 died of cancer and 2 developed a recurrence. Of 32 patients undergoing polyp excision, 20 were followed up; 3 died of cancer and 4 developed recurrences.

1182 BIOCHEMICAL CHANGES IN THE BRAIN DURING REFLEXES CAUSING DYSTROPHY OF THE GASTRIC MUCOSA. (Rus.) Moreva, E. V. (Inst. Exp. Med., USSR Acad. Med. Sci., Leningrad). Biull. Eksp. Biol. Med. 62(7):49-51, 1966.
In normal rats, the free acetylcholine content of the greater cerebral hemisphere was somewhat higher than in that of the region of subcortical formations, while the bound acetylcholine content was similar in both regions. In immobilized rats, electrical stimulation for 3 hr. produced destructive lesions in the gastric wall, accompanied by a decrease in acetylcholine content in the brain. Bound acetylcholine decreased from 1.2-0.58 $\mu\text{g/g}$ tissue in the subcortical region and from 0.0-0.7 $\mu\text{g/g}$ in the greater cerebral hemisphere; free acetylcholine in these regions decreased from 1.1-0.75 and from 2.1-1.3 $\mu\text{g/g}$, resp. Immediately after prolonged electrical stimulation, the γ -aminobutyric acid content in brain tissue decreased from 16.9-10.2 mg%; it returned to normal 15 min. after the end of stimulation. Neither amysil (3 mg/kg) nor luminal (100 mg/kg), admin. 15-30 min. before stimulation, prevented this decrease. Arecholine, nicotine (M- and N-cholinergics; in doses producing hyperkinesis), amysil, adiphenine (M- and N-cholinolytics; in doses preventing hyperkinesis) had no effect on the γ -aminobutyric acid content of the brain tissue.

1183 CARCINOMA OF THE STOMACH AND EARLY PERNICIOUS ANAEMIA. (E.) Shearman, D. J. C. (U. Edinburgh, Scotland), R. Wilson, N. D. C. Finlayson and R. R. Samson. Lancet 2(7460):403-404, 1966.
Signs of pernicious anemia were studied in 35 cases of stomach carcinoma, 4 of whom already known to have pernicious anemia. Histamine tests were carried out in 25 patients not suspected of having pernicious anemia; 11 showed total achlorhydria, and all but 1 of the other patients showed an acid response of less than mEq in the first 1 hr. after histamine admin. Aside from cases of proven pernicious anemia, 9 other patients showed low serum vitamin B₁₂, although these patients often had normal vitamin B₁₂ absorption. It is suggested that stomach cancer can and does occur in the pre-pernicious state of pernicious anemia, and that the incidence of cancer in relation to pernicious anemia may be underestimated.

1184 ON THE NITROGEN BALANCE AND SERUM PROTEINS AFTER GASTRIC RESECTION. (E.) Sommerfelt, S. C. (U. Oslo, Norway), P. Bjørnstad, B. Fretheim, H. N. Haugen, J. Kofstad, R. Nesbakken and H. Rustad. Acta Chir. Scand. Suppl. 357:117-121, 1966.
Nitrogen balance and serum protein conc. were assessed in patients following gastric resection. Negative nitrogen balance was observed postoperatively (av. 10-25 g/day); there was no significant difference in nitrogen balance between 6 controls and patients receiving a high-caloric diet in the postoperative period; in fact, 4 of these patients had higher urinary nitrogen excretion. Total protein conc. was either unaltered or slightly decreased during the postoperative period; serum albumin decreased, the γ - and β -globulins were unaltered, and the α_1 - and α_2 -globulins increased 2 protein fractions. Total iron binding capacity, measured in patients, showed a slight but definite decrease accompanied by a sharp decrease in serum iron in all cases. These alterations are said to belong to the pattern of reaction which occurs in an organism undergoing an acutely active process.

1185 THE EFFECT OF ZINC BACITRACIN ON PATIENTS WITH TOTAL GASTRECTOMY. (E.) Skåland, K. (State Hosp., Oslo, Norway), B. Bugge-Asperheim, E. Gjone, N. Helsing and J. Myren. Acta Chir. Scand. 132(1/2):180-185, 1966.
The effect of zinc bacitracin (10 mg tablets, 3 doses/day) was studied in 13 patients gastrectomized 8 yr. or more previously for stomach carcinoma. Following pretreatment period of 3 mo., av. body wt. was 0.4 kg lower than before, but after 3 mo. of treatment the av. body wt. rose 1.9 kg. This wt. difference was not statistically significant. No significant difference was found between the

average body wt. of placebo- and zinc bacitracin-treated groups in a double-blind trial in 10 cases. Zinc bacitracin treatment had no significant effect on fecal fat and nitrogen content, which were slightly above normal. Blood hemoglobin, serum proteins, total cholesterol and iron, and bacteriologic findings in stool specimens were unaltered during bacitracin treatment. No adverse effects were noted.

- 11186 CATABOLIC METABOLISM OF CHOLESTEROL IN STOMACH CANCER. (E.) Shinzeki, K. (Okayama U. Med. Sch., Okayama, Japan), M. Narusue and Y. Yamamoto. Acta Med. Okayama 20(1):29-36, 1966.

Cancerous and non-cancerous specimens were removed from the same stomach of patients with carcinoma of the stomach, and the content of free and esterified cholesterol and 5α -cholestan- 3β -ol was determined. In non-cancerous tissues, the ratios of free 5α -cholestan- 3β -ol and cholesterol and esterified 5α -cholestan- 3β -ol was higher in the pylorus than in the cardia, but esterified cholesterol was higher in the cardia than in the pylorus. In cancerous tissues, the ratio of free cholesterol was higher than in non-cancerous tissue, and esterified 5α -cholestan- 3β -ol and cholesterol levels were lower in the cancerous tissues. It is concluded that cholesterol metabolism is more active in cancerous tissues than in non-cancerous tissues.

- 11187 STUDY OF THE ALKALINE COMPONENT OF THE GASTRIC JUICE IN CERTAIN ULCERATIVE FORMS, IN HYPOACIDITY, AND IN ACHLORHYDRIA. (Rum.) Ciplea, A. (Physiol Inst., Rum. Acad. Sci., Bucharest, Rumania), P. Groza and A. Oană. Stud. Cercet. Fiziol. 11(3):253-256, 1966.

The acid and alkaline components of gastric juice were studied in 22 patients with gastric ulcer (10), hypoacidity (7), and achlorhydria (5) in a resting stage, after intubation, and at various times after challenge with histamine. Individual variations of the acid and alkaline components of the gastric juice were seen, depending mainly on the number and functional integrity of secretory cells. In the ulcer patients, acid secretion neutralized completely the alkaline component, but the latter sometimes appeared in excess in the resting juice; in such cases, it also increased after histamine challenge. In hypoacidity, the alkaline component was preponderant, and remained so even after histamine admin., except for a short initial period immediately following the challenge; this may indicate a reduction in the number of acid-secreting cells. In achlorhydria, acid-producing cells were obviously absent, and partial neutralization of the alkaline component (in some cases) was due to the presence of organic acids found in the mucous secretion. Histamine had no effect on acid-alkaline excretion ratios in the gastric juice in achlorhydria; it is concluded that histamine cannot initiate acid secretion where it did not exist before, but can only promote existing secretion. Study of the gastric alkaline component is therefore of importance in the differential diagnosis of true achlorhydrias, and is also a good measure of gastric mucous secretion.

- 11188 FREDET-RAMSTEDT PYLOROPLASTY TO COMPLEMENT VAGOTOMY. (E.) Linn, B. S. (U. Miami Sch. Med., Fla.), J. Jiminez, W. R. Canaday, Jr. and M. W. Wolcott. Surgery 60(4):891-893, 1966.

Bilaterally vagotomized dogs underwent no further surgery (Group 1; controls), Fredet-Ramstedt pyloroplasty (Group 2), or Heineke-Mikulicz pyloroplasty (Group 3). The additional pyloroplasty in Groups 2 and 3 required 3.3 and 33.5 min. to perform, resp. Dogs in all groups had uneventful postoperative courses, with no significant difference in wt. changes. At the end of 2 hr., Group 1 had 60% retention of stomach content, Group 2, 24% and Group 3, 31%. On postmortem examination, stomach vol. was greater in Group 2 (314 ml) than Groups 1 or 3 (290 and 275 ml, resp.); differences between full and empty stomach wt. of the groups were statistically significant, but no confident explanation of these differences could be made. It is concluded that Fredet-Ramstedt pyloroplasty may be clinically useful for patients without pyloroduodenal disease who need a drainage procedure to complement vagotomy.

- 11189 ENTEROANASTOMOSIS WITH PARTIAL GASTRECTOMY IN TREATMENT OF POSTCIBAL SYMPTOMS. PROTECTION AGAINST DUMPING SYNDROME AND DIARRHEA. (E.) Dahlgren, S. (U. Uppsala Hosp., Sweden). Am. Surg. 32(9):615-618, 1966.

Postoperative studies were conducted in 220 patients 1-6 yr. after Billroth II partial gastrectomy (approx. 67% of the stomach was removed and an antecolic gastroenterostomy performed, usually to the entire cut end of the stomach). In 90 of these cases, an enteroanastomosis between the afferent and efferent loops was made. The incidences of postoperative symptoms in patients undergoing gastrectomy with and without enteroanastomosis was: chronic (mild to severe) afferent loop syndrome (postprandial vomiting of bile) 3.3% and 21.5%, resp.; mild to severe afferent loop syndrome (dumping, tiredness, and weakness after meals) 13.3% and 1.5%, resp.; and diarrhea 0% and 7.7%, resp. The differences between the two groups regarding chronic afferent loop syndrome and diarrhea were statistically significant. Enteroanastomosis is recommended in patients undergoing partial gastrectomy with antecolic gastrojejunostomy.

- 190 SPHINCTER RESERVING DISTAL GASTRECTOMY. (E.) Katsumi, M. (Wakayama Med. Coll., Japan), A. Nishigaki and M. Okada. Wakayama Med. Rep. 10(4):165-169, 1966.

A new modification of the Billroth I gastrectomy to prevent the dumping syndrome is described. In dissecting the pylorus, a circumferential incision through the mucosa and the muscular layers is made 7-8 mm proximal to the ring of pyloric circular muscle. The mucosal layer is separated from the muscular layer distal to the ring of circular muscle for 2-3 mm, and the mucosal layer cut off at the duodenal boundary. At the same time partial resection of the sphincter muscle can be performed as desired by the surgeon. At anastomosis, the gastric stump (formed from a band of mucosa 10 mm wide) is fitted into the ring of pyloric muscle; 2-layered sutures are used, 1 for the mucosa and another for the sero-muscular wall. The suturing of the mucosa can be done without damage to the pyloric sphincter; pyloroplasty is unnecessary. One clinical case is described. A man with indications of an early cancer on the anterior wall of the lesser gastric curvature underwent resection of the distal 67% of the stomach, using the described procedure. Neither the dumping syndrome nor any signs of stenosis at the anastomosis were seen postoperatively; fluoroscopic examination 1 mo. after surgery revealed a sphincter with excellent functional characteristics.

- 191 PYLORIC STENOSIS. THE INCIDENCE OF INFANTILE HYPERTROPHIC PYLORIC STENOSIS IN THE NEGRO INFANT. (E.) Hara, S. (Meharry Med. Coll., Nashville, Tenn.), E. P. Crump and W. G. Parker. J. Nat. Med. Assn. 58(4):250-253, 1966.

Twelve surgically confirmed cases of infantile hypertrophic pyloric stenosis occurred over a 10-yr. period in 13,075 Negro infants, an incidence of 0.92/1000. This rate, while lower than that reported for Sweden (4/1000) or white Americans (2.26/1000), was higher than that previously reported for Negro Americans (1.48/1000). In this group males outnumbered females 11 to 1; 50% were first born, and 75% of the mothers were 25 yr. old or more. Vomiting, the initial sign, occurred at age 2 wk.-2 mo.; an abdominal mass was palpated in 11 cases. It is concluded that the condition varies in frequency from 1 ethnic group and population to another, but the cause of this variation, as of pyloric stenosis itself, remains unsolved.

- 192 ON SO-CALLED VENOSTATIC GASTRITIS IN CONGESTIVE HEART FAILURE. (E.) Fixa, B. (Charles U., Hradec Kralove, Czechoslovakia), O. Komárková, V. Jurkovič and V. Herout. Cardiologia (Basel) 48(5):471-478, 1966.

The incidence of chronic gastritis was 52% in 25 patients with signs of right-sided congestive heart failure, compared to 73.9% in 23 patients with fully compensated cardiac disease. The difference was not statistically significant. When the abnormal gastric morphology was further subdivided into superficial gastritis, atrophic gastritis and undefined gastritis, the incidences in the 2 groups were 10.0% and 43.5%, 32.0% and 17.4%, and 4.0% and 13.0%, resp. These data would negate the usage of the term venostatic gastritis. The incidence of dyspeptic complaints was higher in patients with congestive failure (68.0%), compared to 31.1% in patients with compensated cardiac disease. It is concluded that congestive heart disease has no apparent causal relationship with chronic gastritis.

STOMACH

- 11193 STUDIES OF THE DIAGNOSTIC VALUE OF GASTRIC JUICE SECRETION EXAMINATION, ACCORDING TO LAMBLING, ON THE BASIS OF BIOPTICALLY CERTAIN CASES OF GASTRITIS. (Ger.) Bergmann, M. (Friedrich-Schiller U., Jena, Germany). *Zschr. Ges. Inn. Med.* 21(14):174-176 & 433-435, 1966.

The Gassmann modification of the Lambling technic for the analysis of gastric juice is the method of choice for ambulatory patients. The value of this technic in the diagnosis of gastritis was reassayed in comparison to biopsy diagnoses of specimens from 39 normal individuals and 187 patients with gastritis. The grouping of 39 normal persons and 49 persons with gastritis atrophicans with regard to production of free HCl/hr. resulted in an asymmetrical graph; this also occurred in the analysis of Gassmann's cases. There was only a moderate correlation ($r = 0.46$) between the free acid production/hr. and the morphological findings; in this group of 226 cases there was agreement between the 2 methods in 158 and no agreement in 68 cases.

- 11194 TREATMENT OF POST-GASTRECTOMY IRON-DEFICIENCY ANAEMIA WITH REFERENCE TO THE ABSORPTION OF IRON ADMINISTERED IN FLUID AND TABLET FORM. (E.) Krause, U. (U. Uppsala, Sweden). *Acta Chir. Scand.* 132(1/2):186-194, 1966.

Ferroglycine was admin. in 10-day courses, alternating as tablets or soln. (80 mg/day labeled with 2 μ C Fe⁵⁹ and 13 μ C Fe⁵⁵, resp.), to 11 patients following Billroth II gastrectomy and 10 patients after the Billroth I gastrectomy, none with grave anemia (hemoglobin 70% or over). The activity of the 2 isotopes and the absorption quotient were determined 2 wk. after the last dose. Another group of 10 patients (6 Billroth I, 4 Billroth II) received the same doses of ferroglycine, except that it was always admin. in soln. On alternate days the soln. was tagged with Fe⁵⁵-containing sorbitol or with Fe⁵⁹-containing glucose. In the first group, the fluid preparation (containing Fe⁵⁹ stabilized with sorbitol) was absorbed 50% better than the tablets in the Billroth II patients; in the Billroth I patients, the fluid was absorbed 43% better than the tablets. In the other group, the sorbitol-stabilized iron soln. was absorbed 60% better than the glucose stabilized soln. In 5 patients with grave anemia receiving the same treatment, absorption was also better with the sorbitol-stabilized soln. It is concluded that the superior absorption of the soln. is due to the sorbitol content. This difference, however, is not large and tablets are probably satisfactory in clinical practice. In patients with decreased intestinal transit times, iron should be admin. in soln. Iron in tablets is probably more efficiently absorbed if the tablets are taken lying down or upon going to bed.

- 11195 COMPLICATIONS OF TUBE GASTROSTOMY IN INFANTS AND CHILDREN. 15-YEAR REVIEW OF 240 CASES. (E.) Haws, E. B. (U. Pittsburgh Sch. Med., Pa.), W. K. Sieber and W. B. Kiesewetter. *Ann. Surg.* 164(2):284-290, 1966.

In 234 infants and children (179 were newborn) undergoing 240 tube gastrostomies over 15 yr., esophageal atresia with tracheoesophageal fistula was the most common indication in newborns (137 cases), while upper gastrointestinal atresias and annular pancreas accounted for 27 additional cases. Esophageal varices and stenosis or stricture accounted for most cases in older infants and children. Nine Witzel gastrostomies were performed; the remainder were Stamm-type gastrostomies performed through a short transverse or vertical left upper quadrant muscle-splitting incision. Major complications such as separation of stomach from the abdominal wall upon tube reinsertion, spontaneous fluid leak into the peritoneum, and uncontrollable external stoma leakage, occurred in 14 patients (5.8%), of whom 11 died. Minor complications (prolapse of tube into the duodenum, infection, and stomal leaks) occurred in 26 cases (10.8%), 1 of whom died. Prematurity was the major factor predisposing to gastrostomy complications, doubling the expected incidence. Gastrostomy stomas closed spontaneously in 80% of surviving patients after removal of the tubes.

- 11196 CRITICAL EVALUATION OF RADIOLOGIC FINDINGS IN ESSENTIAL PYLORIC HYPERTROPHY. (It.) Borgherini, A. (U. Padua, Italy), M. Della Mea and G. Fassetta. *Acta Chir. Ital.* 21(6):949-968, 1965.

study of clinical, radiologic and operative findings in 45 cases of congenital hypertrophic pyloric stenosis showed that the onset of projectile vomiting occurred between 7-34 days of life (av. = 18), in the presence of total (28 of 45) or partial (16 of 45) obstipation. Tympanites was demonstrable in 10 of 45; a secondary horizontal peristaltic wave moving toward the right hypochondriac region, in 10 of 45. Pyloric tumors were palpable in 10 of 45 and almost all patients showed normo- or hypochromic anemia, an increased WBC count without significant changes in leukocyte formula, dehydration and other evidences of deterioration of general status. The male-female ratio was 37:8. Characteristic X-ray findings included absence of reduction of the amount of gas usually contained in the intestine, distention, distectasia, intermittent hyperperistalsis alternating with significant diminution of the frequency and amplitude of the peristaltic wave, diminution of the thickness of the stomach wall, and modifications of both gastric and pyloric curvatures due to increased antral pressure, compression by other organs, etc.

- 97 MECHANISMS OF FUNDO-ANTRAL AND ANTRO-FUNDAL GASTRIC REFLEXES. (Rus.) Bogach, P. G. (Shevchenko U., Kiev, USSR) and S. D. Groisman. Fiziol. Zhur. SSSR Sechenov. 52(5):512-520, 1966.

Dogs with gastroenterostomies and fundic or pyloric fistulas, but with intact vagus nerves, admin. of insulin (7-16 U s.c.) stimulated the motor function of the pylorus and (to a lesser extent) fundus after 40-60 min. The general condition deteriorated after 80-100 min. Glucose (200 ml of 20% soln. intragastrically) markedly depressed pyloric contraction; removal of the pyloric vagus nerves had no effect on pyloric contraction, despite the stimulation of the fundus and clinical signs of hypoglycemia. Resection of the neurovascular nodules resulted in complete preservation of the isolated pylorus on that side; additional section of the splanchnic nerve and removal of the abdominal sympathetic chain abolished the inhibiting reaction and motor unrest induced by air in the stomach. The fundus-antral and antro-fundal inhibitory reflexes were not affected by resection of the neurovascular nodules when the fundus and pylorus were stimulated mechanically. These 2 reflexes seemed to be involved in a neurological bypass, which was fastest at the solar ganglion, when the pylorus was isolated. The threshold and after-effect period of the antro-fundal inhibitory reflex were increased by bilateral splanchnicotomy and removal of the abdominal sympathetic chains.

- 98 THE RESISTANCE OF BOWEL USED AS A PEDICLE GRAFT FOLLOWING GASTRECTOMY IN DOGS. (E.) Neto, M. X. (Huron Road Hosp., Cleveland, Ohio). Int. Surg. 46(3):262-268, 1966.

Small and large intestine showed a difference in their resistance to a constant hydrochloric acid stimulation when they were used to replace a partially (75%) removed stomach in dogs. In these experiments, either a piece of the small or of large intestine was selected to replace the removed stomach portion and it was stomosed between the remaining stomach and the duodenum; then, following a 3-day period for recovery, the dogs received a daily s.c. inj. of 30 mg of histamine for 30 days. In the group with jejunal transplant, peptic ulceration was present in all but one which had survived only 5 days of histamine inj. In the 2 dogs with terminal ileum transplants, 1 developed ulceration and the other expired after only 7 days of histamine inj. Apparently, the various segments of the small intestine are uniformly affected by chronic histamine stimulation. In the group of dogs with a large intestine transplant, ulceration occurred in all; in 3 dogs the ulcer perforated with subsequent death 3, 6 and 13 days following the chronic histamine stimulation. The ulceration process was always at the proximal margin of the graft, just distal to the anastomosis.

- 99 BENIGN LYMPHOID HYPERPLASIA OF THE STOMACH AND DUODENUM. (E.) Perez, C. A. (Washington U. Sch. Med., St. Louis, Mo.) and R. F. Dorfman. Radiology 87(3):505-510, 1966.

Lymphoma of the stomach in 15 patients was diagnosed radiographically into the following categories: (1) tumor mass with ulceration (5 cases), (2) constricting or infiltrating lesion (4 cases), (3) isolated, well defined ulcer crater (4 cases), (4) enlarged gastric rugae (2 cases) and (5) normal (1 case). The

STOMACH

histologic picture was one of fibrous tissue replacement of smooth muscle adjacent to the ulcer with a dense infiltration of mature lymphocytes; lymphoid germinal centers were frequently seen as part of the lesion. Regional lymph nodes exhibited varying degrees of reactive hyperplasia. Radiographically pseudolymphoma may simulate any of the diverse types of malignant tumors such as carcinoma, lymphoma, or sarcoma. Almost invariably it is associated with either gastric or duodenal peptic ulceration and with a smooth filling defect with a preserved surrounding mucosal pattern. The diagnosis is usually clear cut in the presence of an inflammatory filtrate chiefly of mature lymphocytes but including plasma cells, eosinophils, with true lymphoid germinal centers and without evidence of lymph node involvement, in a patient with chronic peptic ulceration. The recognition of this lesion is important if radical therapeutic measures are to be avoided; it is also important for the critical evaluation of the response to therapy in patients with gastric malignant lymphoma.

- 11200 AN EVALUATION OF JEJUNAL INTERPOSITION RECONSTRUCTION AFTER TOTAL GASTRECTOMY IN DOGS. (E.) Lawson, D. W. (Nat. Naval Med. Ctr., Bethesda, Md.), A. J. Defalco, B. E. Bradley, G. C. Vineyard and J. E. McClenathan. J. Surg. Res. (Boston) 6(6):240-246, 1966.

Healthy adult mongrel dogs (17-29 kg) were used to compare the efficiency of 3 methods of esophagojejunal anastomoses, following a rigorous series of preoperative preparations and tests including baselines for wt., hematocrit, hemoglobin, serum Fe, total plasma protein and albumin-globulin ratio; pancreatic activity and absorption of carbohydrate and amino acids were determined by the gelatin-xylose test; measurement of Fe absorption was made by radioactivity. The 3 types of reconstruction were: Group 1, end-to-side esophagojejunostomy with side-to-side entero-enterostomy between the jejunal loops; Group 2, Roux-en-Y anastomoses; Group 3, an anticolonic, antiperistaltic jejunal interposition between esophagus and duodenum; the jejunal segment interposed was 12-18 in. in length, supplied by 2 major arterial arcades, and required partial mobilization of the ligament of Treitz. All anastomoses were 2-layered. With extensive postoperative care 19 dogs survived these procedures, including 7 in Group 1, and 6 each in Groups 2 and 3. All preoperative tests were again performed 2 mo. after gastrectomy. RBC indices and reticulocyte counts were also made to investigate postoperative anemia. After completion of studies, animals were sacrificed at periods ranging from 2-6 mo. after gastrectomy. Av. wt. loss was: Group 1, 29% of preoperative wt., Group 2, 31%; Group 3, 27%. Malnutrition occurred in all dogs; serum albumin levels fell to 1.8 g in Group 1, to 2.1 in Group 2 and to 2.3% in Group 3, statistically not significant between groups. Decreased absorption of carbohydrate and amino acids (in terms of xylose and hydroxyproline in urine) occurred to about the same degree in the different groups. The degree of anemia and the depression of Fe absorption also were very much the same for the 3 types of operation. No significant advantage in any measured parameter could be demonstrated for jejunal interposition in reconstruction over the other 2 procedures.

- 11201 ACUTE GASTRIC ULCERS INDUCED BY RADIATION. (E.) Sell, A. (Radium Ctr. for Jutland, Arhus, Denmark) and T. S. Jensen. Acta Radiol. 4(4): 289-297, 1966.

Four cases of acute gastric ulceration were observed following postoperative irradiation of the lumbar lymph nodes in malignant testicular tumors. The unavoidable dose to the gastric mucosa ranged from 4000 to 5000 r/5 wk. in 3 cases and in case 4 it was in 2 courses, the first 1600 r/54 days and the second 4800 r/24 days. The first 3 cases developed large ulcerations (in 2 patients, penetrating), all treated successfully by resection, and all with no recurrence of malignancy. Patient 4 who received a light course of irradiation and then a heavier course developed epigastric pain and hematemesis. An ulcer crater was revealed in the posterior wall on X-ray examination. The ulcer healed under conservative treatment. Six. mo. later the patient died of wide spread metastases. The treatment of acute radiation-induced ulcers, in view of these 4 cases, should presumably be surgical owing to the risk of hemorrhage and perforation.

02 PENETRATED ULCER NEAR THE CARDIA OF THE STOMACH. (E.) Bryk, D. (Maimonides Hosp., Brooklyn, N. Y.). *Am. J. Dig. Dis.* 11(9):728-734, 1966. Penetrated benign ulcer in the region of the cardia of the stomach may cause difficulty in X-ray differential diagnosis. The extent of the inflammatory process, and the stage of development may cause the ulcer to resemble a diverticulum or an ulcerated neoplasm, lesions which are more frequent in this location. X-ray diagnosis is dependent upon the following criteria: (1) trapping of air and fluid within the crater; (2) constancy in ulcer size, unaffected by peristaltic activity; (3) extension of the crater for a significant distance outside the contours of the stomach; (4) evidence of perigastric inflammatory reaction. Characteristics of diverticula are: changes in size and contour during gastric peristalsis, presence of mucosal folds (not in all), neck usually narrow. Two distinguishing features of carcinomas of the cardia are: eccentric situation of ulceration (usually centrally located in associated mass of benign ulcer) and irregular configuration of penetrated malignant ulcer. X-ray studies of 3 benign penetrated ulcers and 1 penetrated ulcerated malignancy are presented to emphasize certain differential features.

03 CARBOHYDRATE METABOLISM IN THE SUBTOTAL GASTRECTOMY PATIENT. (E.) Berkowitz, D. (Hahnemann Med. Coll., Philadelphia, Pa.) and S. Glassman. *Am. J. Gastroent.* 46(2):119-129, 1966. Twenty patients were given glucose tolerance tests before and after subtotal gastrectomy. Following the ingestion of 100 g of glucose the mean peak value was 165 mg% and the 2-hr. mean value 74 mg% prior to surgery. After surgery the mean peak value was 218 mg% and the 2-hr. mean value 106 mg%. These marked differences were also shown in rapidity of change in 13 patients studied after surgery, the mean increase at 20 min. being 62 mg% and the mean increase at 40 min. 100 mg%. Diabetic dumping symptoms occurred in each subject, the severity of the reaction being proportional to the rate of increase in blood glucose. Ten postoperative patients who received 1 g of tolbutamide p.o. before the ingestion of glucose had significantly lower blood glucose levels; the mean value at 20 min. showed an increase of only 32 mg%; the dumping syndrome was correspondingly less severe. Plasma glucose changes were measured before and after glucose ingestion using a plasma labeled with radioactive iodine; plasma vol. decreased as the blood sugar increased. Tolbutamide, by reducing the blood sugar conc., tended to retain blood volume. The chronic admin. of tolbutamide (0.5-1.0 g) given 1-3 times daily before surgery to 15 subjects with disabling dumping syndromes caused definite improvement in 9 leading to increase in wt.; 6 showed no significant improvement. Tolbutamide was effective in subjects operated upon at least 24 mo. previously. There is some evidence that the changes which cause dumping may predispose to diabetes.

04 CHANGES IN BLOOD VOLUME, PLASMA VOLUME AND RED CELL VOLUME FOLLOWING GASTRIC RESECTION. (E.) Rustad, H. (U. Oslo, Norway), P. Bjørnstad, B. Fretheim, H. N. Haugen, J. Kofstad, R. Nesbakken and S. C. Sommerfelt. *Acta Chir. Scand. Suppl.* 357:127-135, 1966. The effects of blood loss in patients undergoing gastric resection were compared to the effects of venous bleeding in blood donors. Following withdrawal of 450 ml of blood from donors the vol. dropped, RBC/plasma balance was unchanged. Hemodilution occurred during the next 30-60 min. causing an increase in vol. (hemocrit dropped). The increased vol. disappeared rapidly within the next few hr. Blood vol. was restored within 24-36 hr. by protein-rich fluid, RBC were replaced within 15-30 days. Following gastric resection, without transfusion, a decreased vol. was seen. The initial dilution did not occur. During the next 12-24 hr. hemoconcentration occurred but as a result of decreased plasma vol. Blood vol. slowly expanded for 2-3 days postoperatively; by 3-4 days vol. was normal. RBC vol. slowly increased after 3 days over a period of 8-10 wk. Blood vol. was maintained in a group of patients receiving blood replacement. There was moderate hemoconcentration in the first 48 hr. These patients had a tendency to oliguria. It was concluded that patients exposed to this type of surgery lose an estimated 300-400 ml plasma which should be replaced. Even with blood replacement the patients had oliguria and hemoconcentration; additional fluid therapy is indicated in such cases. It is pointed out that

STOMACH

blood drawn for tests (as in this study) may significantly lower blood vol. and should be compensated for at intervals during a lengthy study.

- 11205 JEJUNAL TRANSPOSITION (JT) AS A ROUTINE METHOD IN STOMACH SURGERY. (E.) Hedenstedt, S. (Nacka Hosp., Sweden). Acta Chir. Scand. Suppl. 357:181-185, 1966.

Eight yr. experience with jejunal transposition in 700 cases are summarized. Primary jejunal transposition with vagotomy was performed in 190 cases of gastric ulcer, 329 cases of duodenal ulcer and 80 cases of carcinoma of the stomach. Secondary jejunal transposition was performed in 101 cases of dumping syndrome after Billroth I and II operations and 1 case of total gastrectomy. Mortality for primary jejunal transposition was 1.5%, for secondary jejunal transposition, 2%. Ruling out cases undertaken under acute conditions, mortality was 0.75%. In part of the series with jejunal transposition with selective vagotomy analyzed (N=345) diarrhea occurred in 11% of the patients. The rate of stomal ulcer was 0.5%. Selective vagotomy reduced the frequency from approx. 50% following total vagotomy to approx. 10%. The dumping syndrome was previously reported to be considerably lower following jejunal transposition compared with Billroth I or II operations. Generally, following jejunal transposition, dumping occurred in approx. 25% of the cases, following published Billroth II in 50-60% of the cases. Dumping was dramatically reduced following transposition in disabled Billroth I and II patients. The incidence of anemia, sideropenia, and steatorrhea were all reported to be decreased. In a study of 42 cases of Billroth I and II operations, 16 reoperated with jejunal transposition indicated that vitamin B₁₂ absorption was corrected after jejunal transposition, suggesting that the disturbed absorption is not due to atrophy but malabsorption. X-ray studies showed a sphincter-like mechanism of the jejunal segment. It is recommended that jejunal transposition be considered for general use other than for treatment of severe dumping cases and malnutrition. In favor of the method is the low mortality, the small risk of stomal ulcer, low frequency of dumping and the diminution of malabsorption. The method should, of course, be compared with modern selective vagotomy methods.

- 11206 STEATORRHEA IN PATIENTS WITH SEVERE, ATROPHIC, CHRONIC GASTRITIS. (Sp.) Saredi, R. J., A. R. Lopez, A. M. Musso, R. Sabagh, H. Gotta and M. M. Ramos Mejia. Prensa Med. Argent. 53(20):1107-1110, 1966.

Admin. of Kay's Test and Schilling's Test confirmed the presence of steatorrhea in 7 of 16 patients with atrophic chronic gastritis, including 6 of 9 with Schilling percentages below 15, and in 1 patient suffering from idiopathic atrophic gastritis and showing a Schilling percentage of 13.6. There was no discernible relationship between the incidence of steatorrhea and the degree of structural or functional deficit or the amount of free hydrochloric acid produced after max. histamine stimulation. It is concluded that the physiopathologic mechanisms involved in the genesis of steatorrhea in the presence of atrophic chronic gastritis need further investigation.

- 11207 A TEST FOR PYLORIC REGURGITATION. (E.) Capper, W. M. (Southmead Hosp., Bristol, England), G. R. Airth and J. O. Kilby. Lancet 2(7464):621-623, 1966.

Since the presence of bile in aspirated gastric juice is not considered a reliable guide to the amount of duodenal reflux because regurgitation may result from the presence of the indwelling gastric tube, a radiographic method for the detection of pyloric-regurgitation was developed. Soft rubber tubing equipped with a finger coil at the end containing 0.5 ml mercury was passed by swallowing and body positioning into the duodenum. Position of the tube was verified by X-ray. Barium suspension (30 ml) was inj. via an aperture approx. 7.5 cm from the tip of the tube, into the duodenum. The amount of regurgitation was recorded by X-ray and graded for severity. Frequency of peristaltic waves was timed with a stop watch. No reflux was seen in any of 15 normal patients studied. In 19 of 29 patients with gastric ulcer, there was moderate or gross reflux. In 9 of 27 duodenal ulcer patients, reflux was noted. Five of 6 patients with achlorhydria showed reflux. The degree of reflux through the pylorus was found to be proportional to the amount of peristalsis, particularly retroperistalsis in the duodenum.

STOMACH

- 1208 SERUM LIPID LEVELS IN HUMANS FOLLOWING GASTRIC RESECTION. (E.) Björnstad, P. (U. Oslo, Norway), B. Fretheim, H. N. Haugen, J. Kofstad, R. Nesbakken, H. Rustad and S. C. Sommerfelt. Acta Chir. Scand. Suppl. 357:122-126, 1966.

After summarizing present theories of lipid transport, data on 10 patients are reported. All patients had a gastric resection for gastric or duodenal ulcer. The patients were on unrestricted nutritional intake preoperatively but were on deficient diets postoperatively. Conc. of free fatty acids (FFA), triglycerides, phospholipids, and cholesterol were determined 8 days preoperatively and 10 days postoperatively. FFA conc. preoperatively was 0.50 mEq/liter; an increase occurred immediately following surgery and was maintained for 10 days; although FFA levels did decrease with time the high conc. were concluded to be due to increased mobilization of depots caused by increased secretion of adrenal hormones. The triglyceride level was 106 mg/100 ml preoperatively, dropping immediately postoperatively for 2 days; by day 4 the levels exceeded the preoperative levels. A small drop in serum cholesterol was seen following surgery. The phospholipid conc. dropped slightly from the preoperative level of 220 mg/100 ml. These observations were taken to indicate that the organism is able to mobilize its endogenous caloric reserves satisfactorily following surgery. If the patient's nutritional state is satisfactory, exogenous caloric supplement should be unnecessary.

- 1209 REGULATION OF EMPTYING OF THE STOMACH AFTER GASTRIC RESECTION ACCORDING TO BILLROTH I OR II. (E.) Borgström, S. (U. Lund, Sweden) and M. Arborelius. Acta Chir. Scand. Suppl. 357:200-205, 1966.

Intraluminal pressures were measured via water-filled tubes (4 points 3 cm apart) in the duodenum and jejunum during cinematography (roentgen image intensifier) following admin. of contrast medium. The passage of a bolus of the medium through a segment of the intestine was not attended by a change in intraluminal pressure. A pressure wave rose in the empty segment of intestine after the passage of a bolus travelling 3-4 cm/second, followed by repeated stationary waves preventing the inflow of the contrast medium. The stationary waves tended to be antiperistaltic following instillation of oil into the segment. Billroth I patients showed essentially identical patterns, the waves were lower and less well defined. In the afferent loop of Billroth II patients the primary wave pattern was present; the later waves were complex and sometimes were retrograde, breaking the bolus into small portions. Inj. of 20 ml of 50% glucose soln. was followed by marked propulsive activity. An anticholinergic inhibited movements of the intestine.

- 1210 ELECTRON MICROSCOPE STUDIES ON ADENOCARCINOMA CELLS OF THE HUMAN STOMACH. (Jap.) Enomoto, Y. (Nara Coll. Med., Japan). Nara Igaku Zasshi (J. Nara Med. Assn.) 16(5):509-536, 1965.

The ultrastructure of gastric gland and adenocarcinoma cells in the human stomach was studied by light and electron microscopy; the cells were fixed with formalin followed by osmium tetroxide. In the chief cell, the granular endoplasmic reticulum was larger in amount than in the other 3 gastric fundus cells. The basal and middle portions of the parietal cell were filled with numerous mitochondria, obscuring other cell organelles, but the apical portion contained much agranular endoplasmic reticulum with scattered mitochondria. The parietal cell also showed an intracellular canaliculus having a large number of microvilli, with neither cell organelles nor ribosomes. The mucoid cell, while not always containing microvilli, was characterized by granular endoplasmic reticulum and many secretory granules; it was apparently enveloped by a single-layered limiting membrane. The argentaffin cell was identified by numerous osmiophilic granules 0.13-0.20 μ in diameter, without a limiting membrane, in the cytoplasmic matrix; the Golgi apparatus was more abundant than in the other 3 gland cells. In the gastric adenocarcinoma cell fixed by the double-fixation procedure, the nuclear envelope and plasma membrane were hardly visible, suggesting a different chemical composition from normal cells. There was a linear structure of 45 A diameter in the perinuclear space. The cytoplasm was denser than that of normal cells, due to a dense cytoplasmic matrix, ribosomes and granular endoplasmic reticulum. As degeneration of the cell proceeded,

STOMACH

the periodic acid-Schiff-positive vesicles increased in size and number. Some adenocarcinoma cells occasionally had zymogen-like granules or an intracellular canaliculus.

- 11211 STUDIES ON THE GASTRIC CANCER AT OPERATION USING PROBING END WINDOW G. M. TUBE. (Jap.) Takaoka, Y. (Juntendo U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 34(6):1512-1529, 1965.
Following inj. of P³² (15 μ c/kg) into the antecubital vein 8-12 hr. before operation the probing end window G. M. tube was used for point scanning of gastric lesions pre- and postoperatively. In 29 patients with stomach carcinoma, the count ratio of the diseased to the normal tissue was greater than 3.0 in 4 cases, 2.0-3.0 in 7 cases and 1.0-2.0 in 16 cases. In the serosal surface pre- and postoperatively, 6 of 7 cases had a high count ratio postoperatively; the counting ratio was higher on the mucous membrane than on the serosa. In 2 cases of adenocarcinoma with a central ulcer, the count ratio on the serosal surface was 0.73 and 0.53, resp.; at the mucous membrane, the av. count ratios were 1.04 and 1.22, resp. In 13 cases of peptic ulcer, the av. count ratio was 0.66. In 4 cases of gastric polyp, all count ratios were between 1.0-1.5 at both the mucous membrane and serosa. Four cases with colon carcinoma had ratios over 1.5.

SMALL INTESTINE

- 11285 CONGENITAL ATRESIA AND STENOSIS OF THE SMALL INTESTINE. THE CASE FOR RESECTION AND PRIMARY END-TO-END ANASTOMOSIS. (E.) Louw, J. H. (U. Capetown, South Africa). S. Afr. J. Surg. 4(2):57-64, 1966.
- Analysis of a clinicopathological study of 155 cases of congenital intestinal atresia (included 89 cases with jejunoileal lesions) and experimental production of intestinal atresia in animals demonstrated that jejunoileal atresia was probably due to accidental interference with the blood supply of a segment of the fetal intestine by strangulating obstructions that occur as isolated events during late intrauterine life. Resection of at least 10-15 cm of the proximal dilated intestine and 2-5 cm of distal intestine, with primary anastomosis, was performed in 37 cases of jejunoileal atresia, with a survival rate of 92% (3 deaths). In the first 9 cases, side-to-side anastomosis was performed, with 2 deaths and 3 assorted complications among the survivors. In the subsequent 28 cases, end-to-end anastomosis was done, with a 96% survival rate (1 death). It is concluded that resection and primary end-to-end anastomosis is the treatment of choice in most small intestinal atresias.
- 11286 PERFORATION OF THE BOWEL COMPLICATING PERITONEAL SHUNT FOR HYDROCEPHALUS. REPORT OF TWO CASES. (E.) Wilson, C. B. (U. Kentucky Coll. Med., Lexington) and V. Bertan. Am. Surg. 32(9):601-603, 1966.
- Intestinal perforation, a complication of spinal-peritoneal shunts heretofore unreported, is described in 2 infants with hydrocephalus, 1 of whom died. The operation, done by 2 teams operating simultaneously, connected the subarachnoid space in the region of the cauda equina with the true pelvis by means of a plastic tube firmly placed by surrounding sutures; before January, 1965 polyethylene tubing was used, but since then the more pliable silastic tubing has been employed. An infant with communicating hydrocephalus underwent lumbar-subarachnoid shunt at age 5 mo. He recovered uneventfully from surgery, but during the postoperative period the anterior fontanel became tense due to blockage of the shunt. A ventriculo-pleural shunt was performed 1 mo. after the first procedure and the patient was discharged, but 4 mo. later the polyethylene tubing was passed through the rectum. Clinical and radiographic evidence of small intestinal obstruction and generalized peritonitis were seen at admission 5 days later; laparotomy disclosed obstruction of the terminal ileum by an adhesive band, and a segment of the ileum was gangrenous. The right transverse colon was believed to be the site of perforation. Despite vigorous measures the patient died the same day. The other infant underwent a spinal-peritoneal shunt to correct hydrocephalus at age 6 mo.; 11 mo. later the shunt tubing was passed through the rectum. However, physical examination was normal and the child had no symptoms; she remained in good health during the period of observation, and 2 mo. later the cranial circumference had not increased.
- 11287 EXPERIMENTAL CONTRIBUTION TO THE THERAPEUTIC USE OF DEXTRAN IN ILEUS. (Ger.) Schmidt, W. (Karl-Marx U., Leipzig, Germany), V. Steinert and G. Klappach. Pharmazie 21(5):304-307, 1966.
- In rabbits with ileus produced by ligation of the last ileal loop, treatment with dextran (i.v.; 10 ml/kg of 6% soln. immediately after surgery, repeated 2 hr. before sacrifice; or 3 inj. of 10 mg/kg) had no significant effect on the gross or microscopic appearance of the intestine. Gastric and duodenal contents were analyzed for polysaccharide conc., which ranged from 0.046-0.4%, with no significant differences due to dextran treatment. In fact, dextran levels were lower than in untreated controls. The data lend no support to the theory that dextran is excreted by the gastrointestinal tract. Since i.v. dextran seems to be innocuous under these conditions, it is not contraindicated as a shock preventing agent in patients with ileus.
- 11288 BEHAVIOR OF BASOPHILIC GRANULAR CELLS IN ARTIFICIALLY INDUCED MECHANICAL ILEUS IN THE RAT. (It.) Storace, R. (U. Bologna, Italy). Chir. Pat. Sper. 13(3-4):134-139, 1965.

SMALL INTESTINE

In 3-6-mo.-old Sprague-Dawley rats bearing artificially induced, mechanical ileus, the number of mast leukocytes was counted at different postoperative intervals in the gastric submucosa and that of the bladder and in the mucosa of the duodenum and ileum. A statistically significant difference between experimental animals and controls could not be demonstrated; nor were there any statistically significant differences when animals were grouped in terms of the site of ligature: the terminal ileum, the ileocecal junction, the proximal part of the ascending colon or the distal part of the sigmoid.

- 11289 SYMPTOMS AND MALABSORPTION IN DUODENAL DIVERTICULITIS. (Dan.) Thaysen, E. H. (City Hosp., Aalborg, Denmark), H. O. Bang and O. Brøbeck. Nord. Med. 75(15):415-418, 1966.

Among 17 patients with true duodenal diverticulitis in the absence of other abnormalities of the gastrointestinal tract, 7 of 8 with suspected steatorrhea and 7 of 9 with confirmed steatorrhea showed Escherichia coli, coliform staphylococci, or Proteus in material aspirated from the proximal part of the jejunum. Two of the patients without steatorrhea showed impaired absorption of vitamin B₁₂; 2 with confirmed steatorrhea were not examined bacteriologically. Both achlorhydria and hyperchlorhydria occurred in the patient group. Under treatment with p.o. tetracycline, absorption was normalized in 6 cases.

- 11290 FUNCTIONAL DISORDERS OF THE SMALL INTESTINE IN CERTAIN DISEASES OF THE DIGESTIVE TRACT. (Rus.) Linevskii, Iu. V. (Inst. Med., Donetsk, USSR). Ter. Arkh. 38(5):78-83, 1966.

Absorption times and enzyme activities (enterokinase and alkaline phosphatase) were studied in 10 healthy subjects and in 71 patients with digestive tract diseases. In the normal subjects, enzymatic activity in the intestinal juice increased from the duodenum to the ileum, and the av. absorption time was 38 min. Marked functional disturbances were seen in 21 patients with chronic gastritis; the av. absorption time was 5.3 min. In 15 patients with duodenal ulcers, the av. absorption time was 6.2 min.; enzyme metabolism in the small intestine was also markedly depressed. The nature and degree of functional disorders of the small intestine in 11 patients with chronic enteritis and 14 with nonspecific ulcerative colitis depended upon the severity of the underlying disease; the av. absorption time in the former group was 6.5-9.5 min., and in the latter group it was 4.3-6.0 min.

- 11291 GAS-DISTENSION, DOUBLE-CONTRAST DUODENOGRAPHY USING THE SCOTT-HARDEN GASTRODUODENAL TUBE. (E.) Raia, S. (Royal Free Hosp., London) and L. Kreef. Gut 7(4):420-424, 1966.

An atonic duodenographic technic is described using a double-contrast technic with marked distention of the duodenal loop by means of O₂ insufflation, which enables not only a clearer view of the duodenum but also of the head of the pancreas. On the av. the procedure takes 15 min. With local anesthesia, a double-lumen gastroduodenal tube (Scott-Harden) is placed so that the tip of the inner tube reaches the pyloric canal. Then, a mixture of 16 ml of micropaque and 4 ml of water is inj. into the inner tube; in this way only a minimal amount of barium escapes to the stomach. With this visualization, the inner tube is passed further into the second part of the duodenum and then the patient is admin. 4-6 mg of oxyphenonium i.v. while the remainder of the barium mixture is being admin. This is followed by a slow inj. of xylocaine: the duodenum becomes flaccid and immobile within min. Then, forced O₂ insufflation is produced for 3-4 seconds while a film is taken of the distended duodenum, during which time the discomfort is minimal. Any irregular duodenal margin, loss of folds or indentation of the medial portion of the duodenal loop are easily visualized (associated with a pathological pancreas), as are lesions within the duodenal loop itself. (It is also hoped that the rare carcinoma of a diverticulum would be diagnosed by this method.)

- 11292 RADIATION DAMAGE AND REPAIR IN THE HUMAN JEJUNAL MUCOSA. (E.) Wiernik, G. (St. Thomas's Hosp., London). J. Path. Bact. 91(2):389-393, 1966.

Biopsy specimen obtained after various regimes of cobalt irradiation were assessed for histological appearances, for the appearances of the mucosa under the dissecting

SMALL INTESTINE

microscope, and for the changes in the villus. Preirradiation biopsy specimen showed tall finger-like villi covered with a layer of adult epithelial cells and with crypt structures regular and communicate with the side of the villus. After 24 hr. at a dose of 800 r the crypts showed evidence of radiation damage with nuclear irregularity, and after 6 days at 800 r the cellular architecture became abnormal. The crypt cells had become dilated at the base, lost continuity with the sides of the villus, and showed many pyknotic nuclei and vacuoles. At 8 or 9 days the pattern was similar to 6 days at 800 r, but on day 10 considerable changes occurred. The villi themselves became shorter, the cells toward the tip were irregular, and at the base, zones of cells developed mitotic figures. The crypts became largely hyperplastic with mitotic figures and islands of epithelial cells indicating disintegration of the crypts. On day 17 after an 800-r daily dose of the radiation the overshoot phenomenon was observed with the villi taller and epithelial cells numbering 12% above the pretreated level. The crypt cells were also longer and contained 21% more cells than initially. On day 21 the overshoot had passed its peak with the number of crypt cells fallen toward the preirradiation levels whereas the villi had become still taller. The crypt structures were observed to be abnormal 6 mo. after radiation ceased.

- 11293 DUODENAL VARICES TREATED BY PORTACAVAL SHUNT. (E.) Shearburn, E. W. (Women's Med. Coll. Hosp., Philadelphia, Pa.) and D. R. Cooper. Arch. Surg. (Chicago) 93(3):425-427, 1966.

Two cases are reported with bleeding duodenal varices eventually treated successfully by portacaval shunt. One patient, a 53-yr.-old woman, showed no special pathology with the exception of 3 g% hemoglobin and a hematocrit of 13%. Hematologic consultation revealed evidence of anemia due to blood loss. On further examination a diagnosis of portal hypertension was made. No esophageal disease was found. After 8 days and admin. of 8 U of blood, hemoglobin was only 9 g%. In an exploratory operation varices of the duodenum were discovered and ligated. Except for jaundice the patient recovered well. However, because of continued intestinal blood loss and the diagnosis of portal hypertension, a portacaval end-to-side shunt was carried out. The postoperative course was uneventful. On examination 6 yr. later, her hemoglobin was 14.4% with hematocrit of 42%. There was no evidence of cirrhosis. The second patient, a 50-yr.-old man, with a long history of gastrointestinal bleeding, had a low hemoglobin conc. and hematocrit. On last admission to hospital his hemoglobin was 6 g% and his hematocrit 18%. Stools showed 4+ blood. An exploratory operation revealed vigorous bleeding into the duodenum which had large dilated veins. Portal pressure measurement was 230-250 mm H₂O. On the basis of the findings at hand an end-to-side portacaval shunt was performed. The final portal pressure was 110-120 mm H₂O. The patient recovered from a variety of postoperative complications and was discharged on postoperative day 38 with hemoglobin of 10.1 g% and a hematocrit of 31%. Examination of the patient 2 1/2 yr. later showed him to be relatively asymptomatic. He had gained 20 pounds. His blood count was normal.

- 11294 CLINICAL ANALYSIS OF THE SMALL INTESTINE BY X-RAY CINEMATOGRAPHY. (Jap.) Yamanouchi, K. (Tokushima U. Sch. Med., Japan). Shikoku Igaku Zasshi (Shikoku Acta Med.) 22(1):273-280, 1966.

Activity of the human small intestine was studied by X-ray cinematography in normal subjects and patients with hydroperitoneum, enteritis, adhesions, or tuberculosis of the small intestine. In the normal organ, peristaltic movement spread at 1.5-4.0 cm/second. The diameter of the contracting part was 0.5-1.3 cm, and its length 1.0-4.5 cm; the diameter of the dilatating part was 1.5-3.5 cm, and its length 5.0-8.0 cm. The movement of segmental contraction occurred from oral to anal regions, and later occurred simultaneously with peristalsis. Normal intestinal movement after Gastrografen admin. was similar to that seen in enteritis. The intestinal contents in enteritis passed through at a speed of 1.5-6.5 cm/second, and width of the intestine was 1.9-2.3 cm. In hypersecretion, intestinal contents passed at a speed of 1.5-4.0 cm/second; in diarrhea, it was 3.5-4.0 cm/second. In hydroperitoneum, the loop of small intestine remained in the ascites fluid; rapid peristalsis was identical with that in the normal intestine. In tuberculosis, peristaltic movements were retarded and fewer than in normal peristalsis, showing

SMALL INTESTINE

repeated isoperistalsis and antiperistalsis with a pendulum-like movement of the contents; the non-filled portion, which seemed to be the pathological portion, was dilated by the contents. In the presence of adhesions, movements of the intestinal contents were vicissitudinal. In multiple adhesions, movement of intestinal contents was strongly hindered; the multiply adhesive intestine showed a repeated pendulum-like movement and occasional antiperistalsis.

Peptic Ulcer

- 11340 EXPERIMENTAL STUDIES ABOUT THE RELATIONSHIP BETWEEN LIVER DAMAGE AND STOMACH ULCER. (Ger.) Wohlgemuth, B. (Karl-Marx U., Leipzig, Germany) and E. Schille. Acta Hepatosplen. (Stuttgart) 13(4):193-201, 1966.
The process of ulcer formation was studied in guinea pigs treated with histamine (0.25 mg/100 g/day, but not over 100 mg/day for 72 days, then 2.0 mg/day for 24 days i.m.; av. total 111 mg over 96 days) and sacrificed after 13-96 days of treatment. All animals sacrificed after 96 days had at least 1 ulcer; 3 ulcers were present in 3 animals, 4 ulcers in 3 others, and 1 animal had 9. Liver parenchymal changes were seen in the centrilobular areas after 13 or 35 days and extended to other areas after 60-87 days; the later changes also included nuclear and cytoplasmic vacuolization, foci of necrosis, nuclear abnormalities, and signs of fatty degeneration. At the end of the experiment, marked parenchymal degeneration was seen in some parts of the central and intermediary lobules, together with diffuse fatty degeneration and other pathological signs. The Kupffer cells seemed to be activated. The mitotic index in 5 specimens was 1:500 cells. This association between gastric ulcer and liver cirrhosis was also noted in a 5-yr. autopsy study. Cirrhosis was discovered in 2.9% of cases (305 specimens); gastric or duodenal ulcers or both were seen in 56 cases (18.3%). In patients without cirrhosis, the ulcer incidence was only 4.3%; this difference was statistically significant.
- 11341 INFLUENCE OF SEX HORMONES ON THE GENESIS AND DEVELOPMENT OF EXPERIMENTAL GASTRIC ULCER. (Rus.) Lipovskii, S. M. (Lab. Gastroenterol., Acad. Med. Sci., Moscow). Vrach. Delo (4):6-9, 1966.
Surgery by the modified Shay method induced 419 lesions (227 erosions, 192 ulcers) of the gastric mucous membrane in 49 of 50 female rats, as compared to 251 lesions (132 erosions, 119 ulcers) in 35 of 50 males. This surgery induced gastric lesions in 31 of 55 ovariectomized males and 27 of 41 oophorectomized females, as compared to 28 of 55 of intact males and 24 of 41 intact females. The total number of lesions in treated males and females was 286 (171 erosions, 115 ulcers) and 484 (181 erosions, 303 ulcers), resp.; the incidence in controls was 299 (164 erosions, 135 ulcers) in males and 132 (71 erosions, 61 ulcers) in females. Admin. of estrone (folliculin) to oophorectomized females significantly reduced the amount of lesions in each rat, including ulcers, as compared to intact controls, although the number of lesions was also markedly reduced in intact rats. A significant reduction of lesions was also seen in oophorectomized rats treated with diethylstilbestrol dipropionate (Cyren B; 10 U/100 g/day for 10 days i.m.). Progesterone inhibited the development of ulcers in oophorectomized females, but stimulated gastric ulceration in intact females. Ulcer incidence was increased in ovariectomized and intact males treated with testosterone phenylpropionate, whereas estrone inhibited the development of dystrophic processes in the gastric mucous membrane of male rats.
- 11342 RELATIONSHIPS BETWEEN ARTERIOSCLEROSIS AND STOMACH AND DUODENAL ULCERS. (Ger.) Zschoch, H. (Karl-Marx-U., Leipzig, Germany). Deutsch. Zschr. Verdau. Stoffwechselkr. 26(1):12-14, 1966.
Analysis of 20,776 autopsy specimens showed that mild coronary or generalized arteriosclerosis occurs with about the same frequency in subjects with gastric and/or duodenal ulcers, as in subjects without ulcers. Mild coronary sclerosis was seen in 32.15% of ulcer cases and 31.92% of cases without ulcers. For the patients with mild generalized arteriosclerosis, the ulcer incidence was 19.97% and 20.7%, resp. On the other hand, severe coronary sclerosis, myocardial infarction, and severe, generalized arteriosclerosis occurred more frequently in cases of gastric or duodenal ulcer, or ulcer scars, than in autopsy specimens from patients without ulcers; the incidence (in the above order) in groups with and without ulcers was 40.46% and 32.65%; 19.07% and 14.56%; and 64.30% and 51.51%, resp. All 3 differences were statistically significant. The possible causes of this relationship are briefly discussed.
- 11343 PREVENTION OF ACUTE GASTRIC SHOCK ULCERATIONS IN RABBITS WITH LOW MOLECULAR WEIGHT DEXTRAN, HYDROCORTISONE, METARAMINOL AND PHENOXYBENZAMINE.

(E.) Harjola, P.-T. (U. Helsinki, Helsinki, Finland) and A. Sivula.
Acta Chir. Scand. 132(1/2):166-169, 1966.

In rabbits subjected to hemorrhagic shock (of 15 min. duration), together with tracheostomy, thoracotomy, and left auriculectomy, admin. of low molecular wt. dextran immediately thereafter (to replace 20 ml of blood) resulted in survival of 7 of 10 animals for 24 hr., with no gastric pathology. When 15 min. elapsed before dextran admin., 8 of 10 survived, 2 of them with petechiae. Following 15 min. shock and hydrocortisone admin. (10 mg i.v.), 10 of 14 animals survived 24 hr., 2 with petechiae and 1 with ulceration. Metaraminol inj. into the aorta (titrated to maintain pressure) resulted in a 100% survival; 8 of 10 had petechiae, and 1 had ulceration. Phenoxybenzamine (2 mg) resulted in survival in only 1 of 9 rabbits, which had both petechiae and ulceration. In the control group (surgery and 15 min. shock) 7 of 8 showed petechiae, and 3 of 8 had ulceration.

11344 GASTRIC ULCERS. (E.) Smith, E. B. J. Nat. Med. Assn. 58(5):351-358, 1966.

Analysis of the incidence of gastric ulcer at St. Francis General Hospital in 1958-1963 revealed 430 cases of gastric ulcer, 208 (46%) of which required surgical intervention, with a mortality of 2.4%. The incidence of malignancy in the total series was 3.2%; 14 of the operative specimens (6.7%) were histologically classified as carcinoma of the stomach confined to the mucosa. The 5-yr. survival rate in patients with malignancy was 57%, compared to the overall survival rate of 7% for carcinoma of the stomach. In a review of 4 large series comprising 1000, 1930, 795, and 707 cases, resp., the incidence of malignancy ranged from 9%-13.2%. The av. age in benign ulcer was 53 yr., compared to 54 yr. in malignant ulcer; the male:female ratio was 3:1. The medical and surgical aspects of gastric ulcer are reviewed.

11345 THE EFFECT OF HALIDOR(R) (1-BENZYL-1,1-[3'-DIMETHYLAMINOPROPOXY]CYCLO-HEPTANE FUMARATE; EGYT-201) ON EXPERIMENTAL GASTRIC ULCER IN THE RAT. (Ger.) Hauschild, F. (Karl Marx U., Leipzig, Germany) and P. Wolf. Deutsch. Gesundh. 21(35):1665-1670, 1966.

In fasting rats treated ad libitum with a 20% glucose soln. in drinking water or saline for 16-20 days, the av. ulcer index was 27.60 and 29.76, resp. Addition of a soln. of atropine or Halidor to the glucose soln. (approx. 7 and 60 mg/kg/day, resp.) reduced the av. ulcer index to 14.75 and 16.93, resp. When the doses of atropine and Halidor were increased to 8 and 70 mg/kg/day, resp., the av. ulcer index was reduced to 11.04 and 9.81, resp. In rats treated with serotonin (30 mg/kg s.c., repeated 12 hr. later), the av. ulcer index was 22.75. Treatment with atropine (30 mg/kg s.c.) or Halidor (30 or 70 mg/kg s.c.) reduced the av. ulcer index to 13.52 and 6.10, resp. In these 2 studies, a significant reduction in the gastric ulcer index was seen with Halidor, but the individual differences seen after atropine treatment were so wide that these av. values were not statistically significant. In immobilized rats, the av. ulcer index was 7.07; treatment with atropine or Halidor (same s.c. doses) reduced the av. ulcer index to 0.26 (highly significant) and 3.49 (significant at the 5% level), resp.

11346 LATE RESULTS OF MEDICAL AND SURGICAL TREATMENT OF BLEEDING PEPTIC ULCER. (E.) Serebro, H. A. (Sinai Hosp., Baltimore, Md.) and A. I. Mendeloff. Lancet 2(7462):505-508, 1966.

Of 126 patients followed up for a period of 5-10 yr., only 2 died from peptic causes, both in their third peptic hemorrhage; these patients represented 84% of all such patients admitted during a 4-yr. period. Group (1): 77 patients with duodenal ulcer were admitted with their initial bleeding. Of these, 32 bled again during the follow up period; 14 of these had been treated surgically from the outset, of whom 3 bled subsequently; 15 bled after medical therapy, and were later treated surgically; 6 bled again. Group (2): 25 patients admitted with a past history of bleeding from duodenal ulcer, 22 previously treated medically and 3 surgically; 14 of these were treated medically again; 7 bled again in hospital and were then treated surgically; 11 patients were treated surgically from the outset, and of all those treated surgically, 9 bled again (43%). Group (3): Of 13 gastric ulcer patients 6 were treated surgically, and 2 bled again after gastrectomy. Group (4): Of 8 pyloroduodenal ulcer

patients 6 were treated surgically and 2 patients had an episode of hemorrhage subsequently; 4 patients treated medically did not rebleed. Group (5): 3 patients with combined gastric and duodenal ulcers were treated medically and did not rebleed. Although subtotal gastrectomy may be indicated to save a patient with peptic ulcer from exsanguination, about a third of these patients will bleed again during the next 5-10 yr. The bleeding may recur from any portion of the upper gastrointestinal tract. Patients who bleed from peptic ulceration tend to bleed again regardless of the type of therapy.

- 11347 STOMACH ULCER AFTER LOCAL COLD DAMAGE. (Ger.) Grozinger, K.-H. (Heidelberg Surg. Clin., Germany) and W. Wenz. Radiologe 6(7):270-273, 1966.

Gastric freezing admin. to a 66-yr.-old patient for duodenal ulcer was followed 2 wk. later by severe gastric hemorrhage. Radiological examination and subsequent laparotomy 5 mo. after the treatment showed extensive penetrating ulceration and rigidity of the gastric wall in the area of the lesser curvature. Subtotal resection of the stomach was performed; the patient died postoperatively of bronchopneumonia. In 4 additional patients, hemorrhages occurred following gastric freezing, but could be controlled by conservative measures. Ulcerations of the type described above but on a smaller scale were observed in only one additional case.

- 11348 PEPTIC ULCERS IN AN ESSEX VILLAGE. (E.) Walford, P. A. J. Coll. Gen. Pract. 12(2):164-171, 1966.

A retrospective study of the incidence of peptic ulcers over a 5-yr. period in an Essex village was made. The village was somewhat isolated (50 miles from London) with a stable population of approx. 2,000. In the 5-yr. period 3 new cases occurred (annual incidence 0.25/1000) which is about 6.6% the incidence level reported elsewhere. The annual prevalence rate was 3.5/1000 which was about 25% the expected rate. Loss of working time was small, 17 wk. during medical treatment and 30 wk. for surgical treatment. Hemorrhage occurred in 3 of 17 patients, perforation once in 5 yr. Two patients developed carcinoma of the stomach 10 and 16 yr. after diagnosis. Four of 17 cases were treated surgically. The annual prevalence rate of non-ulcer dyspepsia was 4.2/1000. The combined ulcer dyspepsia rate was 7.9/1000 compared with the reported 16/1000 elsewhere. The ratio of ulcers to dyspepsias was 1:4.4 which compared well to reported ratios of 1:4.5. It is concluded that the incidence of peptic ulcers is remarkably low in this village. The reasons for this are unclear but both occupational and genetic factors are possible explanations.

- 11349 TRANSPOSITION OF THE JEJUNUM AS A ROUTINE METHOD IN GASTRIC RESECTION. (E.) Argren, B. (Røros Hosp., Røros, Norway). Acta Chir. Scand. Suppl. 357:186-189, 1966.

Twenty-eight cases of duodenal or gastric ulcers treated with transposition of the jejunum are reported. Hedenstedt's method was used in all cases. Gastric acidity (stimulated by insulin) was determined before and after operation. The av. free acidity and total acidity before the operation for the duodenal ulcer group was 75 and 88 (mEq) and after surgery, 11 and 46. The av. for the gastric ulcer patients were 81 and 89 before surgery and 6 and 32 after. No postoperative anemia was seen (av. Hb values actually increased postoperatively). No cases of dumping, postprandial hypoglycemia, afferent loop syndrome, etc., were seen. Wt. loss av. 4 kg. Twenty-three of 25 patients were rated as fully recovered and restored to health. It is concluded that the results with jejunal transposition are so encouraging that the method will continue to be used routinely in gastric resection and in the treatment of ulcer.

- 11350 AN ALTERNATIVE AT SELECTIVE SURGERY FOR DUODENAL ULCER: PRELIMINARY RESULTS. (E.) Bergström, H. (Central Hosp., Borås, Sweden) and A. Broomé. Acta Chir. Scand. Suppl. 357:196-199, 1966.

Patients with recurrent duodenal ulcer (122) were evaluated by level of preoperative acid production (Kay's augmented histamine test) and divided into 4 surgical groups: Group 1) 30 mEq/hr. acid--precise antrectomy; Group 2, 30-45 mEq/hr.--precise

antrectomy and vagotomy; Group 3, 45 mEq/hr--hemigastrectomy and vagotomy; Group 4, danger of mortality vagotomy and drainage procedure. All patients were reexamined at 6 wk., 52 1 yr. following surgery. The overall aim was to reduce acid production to 12 mEq/hr. or less and this level was reached in 80 of 95 patients tested at 6 wk. At 1 yr. this level was reached in 45 of 52 patients, 5 of the 7 had value lower than 16 mEq/hr. The acid reduction in Group 3 did not differ significantly from that in Group 2; it is concluded that hemigastrectomy is not particularly effective in further reducing acid production over antrectomy. To date, no recurrence or mortality has been observed; 6 of 52 reported postcibal distress and 23 of 52 reported changes in defecation habits, usually toward normality.

- 11351 SELECTIVE SURGERY FOR DUODENAL ULCER BASED ON PREOPERATIVE ACID PRODUCTION. (E.) Broome, A. (Cent. Hosp., Borås, Sweden) and H. Bergström. Acta Chir. Scand. 132(1/2):170-179, 1966.

Based on published data a secretory level of 12 mEq HCl/hr. was aimed at as the result of selective surgery in 122 duodenal ulcer patients. Acid production was determined at least twice preoperatively after inj. of 0.24 mg histamine/10 kg. Based on acid output the patients were divided into 3 surgical groups: Group I, up to 30 mEq HCl/hr., antrectomy, 25 patients; Group 2, 30-45 mEq HCl/hr., antrectomy and vagotomy, 38 patients; Group 3, over 45 mEq HCl/hr., hemigastrectomy and vagotomy, 32 patients; Group 4, not considered further, due to age or poor condition underwent vagotomy and drainage. The percentage decrease in acid production 6 wk. postoperatively was: Group I, 57.3%; Group II, 84.6%; Group III, 87.5%. One yr. later: Group I, 62.3%; Group II, 91.1%; and Group III, 91.1%. With only 16 exceptions the desired level of acid output was accomplished, and in most of these cases the values exceeded the 12 mEq level by very little. Postcibal disorders were noted in 6 of 52 cases 12 mo. after surgery. Changes in defecation habits occurred in 23 of 52 cases, 5 reported occasional diarrhea. No recurrences were recorded up to 1 yr. after surgery. It was noted that in Group III the partial elimination of the parietal cell mass by hemigastrectomy was of minor importance and that, most likely, antrectomy plus vagotomy would have been adequate.

- 11352 TRANSPOSITION OF JEJUNUM COMPARED WITH B I AND B II. (E.) Nordman, O. (U. Oulu, Finland). Acta Chir. Scand. Suppl. 357:190-194, 1966.

A total of 165 subtotal gastrectomy patients (mainly Billroth I and II and jejunal transposition) operated on over a 6-yr. period were recalled and subjected to examination including tests for the presence of hydrochloric acid in the gastric remnant, and contrast radiography. Laboratory values in almost all cases were normal. Acid was shown only in a few patients. The incidence of dumping, milk intolerance and loss in body wt. was reported to be lowest in Billroth I patients, highest in Billroth II patients, with jejunal transposition patients falling between. The mean hemoglobin values in all groups ranged from 12.7 to 13.4 and Fe values from 93 to 115 µg. The jejunal group had the lowest incidence of anemia, but the differences were not marked. Vitamin A balance and Schilling tests fell within normal limits. The glucose tolerance curves were similar for the 3 groups; no differences in excretion of d-xylose were reported. It is summarized that no conclusions can be drawn from the data presented, work is still in progress and a more detailed report is forthcoming.

- 11353 OBSERVATIONS ON BILLROTH II PARTIAL GASTRECTOMY FOR CHRONIC GASTRODUODENAL ULCER. (E.) Klossner, O. (U. Turku, Finland). Acta Chir. Scand. Suppl. 357:177-180, 1966.

Gastric and duodenal ulcer patients who had undergone a 2/3 gastrectomy (Billroth II) with antecolic gastro-jejunostomy and jejuno-jejunostomy were followed up twice, at 2-11 yr. postoperatively for 924 patients, and 8-18 yr. postoperatively for 788 patients. Excellent and good results were noted in 89% of the patients with gastric ulcer and in 86-92% with duodenal ulcer. Recurrence in the gastric ulcer group was 0.3%, 1.6% in the duodenal ulcer group after radical removal and 9.5% in the duodenal group after "exclusion resection". Pain was mentioned by all patients with recurrent ulcer. In 586 patients (74%) there were no postcibal symptoms; 24% experienced slight distress. The type of ulcer had no bearing on the

frequency or degree of severity of symptoms, nor did the method of operation (radical or exclusion). Approx. 75% of the patients were able to follow a free diet or observed only slight restrictions. It is concluded that in this series the Billroth II partial gastrectomy gave fairly good results, providing the ulcer was removed. It is recommended that the "exclusion" operation be avoided. The 3/3 resection proved satisfactory and few patients suffered postcibal distress.

- 354 EVALUATION OF PARTIAL RESECTION OF THE VAGUS NERVES AS SOLE OR ADJUNCTIVE THERAPY IN THE TREATMENT OF GASTRODUODENAL ULCER. (Sp.) Madden, J. L. (St. Clare's Hosp., New York, N. Y.). Prensa Med. Argent. 52(43): 2721-2726, 1965.

Results of treatment were tabulated as excellent, good, or failure in 2 patient groups treated by partial vagotomy and followed long enough to permit adequate evaluation: duodenal ulcer = 50 of 80, 4 of 80 and 26 of 80, resp.; gastric ulcer = 3 of 14, 1 of 14 and 10 of 14, resp. There were no operative mortalities among a total of 146 patients treated. Among 30 of 36 failures which were followed, subsequent intervention was successful in 19, with no operative mortalities. Similar tabulations of treatment results for patients who could be followed after vagotomy as an adjunct to gastrojejunostomy were 155 of 204, 7 of 204 and 42 of 204, with 9 operative mortalities among a total of 273 patients treated. Twenty-four of 25 failures which were followed responded to subsequent intervention, with no mortalities. Similar tabulations for patients who could be followed after vagotomy as an adjunct to hemigastrectomy were 17 of 18, 1 of 18 and 0 of 18, resp., with no operative mortalities among a total of 20 patients treated. In patients who could be followed after vagotomy as an adjunct to pyloroplasty, 23 of 28 showed satisfactory results and 5 were failures. There were 3 operative mortalities among a total of 40 patients who underwent total vagotomy plus pyloroplasty, but none among 10 in whom pyloroplasty was accompanied by selective vagus-nerve transection at the level of the stomach. It is concluded that the best results were seen in the patient group receiving vagotomy as an adjunct to hemigastrectomy; that a relatively high failure rate (24% for all patient groups combined) and a strong tendency toward persistent postoperative diarrhea and malabsorption syndrome make the technic unsuitable for routine use, although it has considerable potential value in the treatment of so-called marginal ulcers occurring post gastrectomy.

379 REGIONAL ENTERITIS (CROHN'S DISEASE). (E.) Fone, D. J. (Royal Melbourne Hosp., Australia). Med. J. Aust. 1(21):865-873, 1966.
In 41 cases of regional enteritis (22 females, 19 males; age 10-64 yr.), the highest incidence was in the 11-30 yr. age group. Approx. 50% had symptoms of 1-5 yr. duration; 13 were diagnosed within 3 mo. In 31 cases the terminal part of the ileum was involved, although multiple sites were common; the colon was affected in 7 cases. Small intestinal lesions were characterized by narrowing of the lumen, thickening of the wall, adhesions, mucosal ulceration, thickening of the mesentery, and lymphadenopathy; they usually terminated abruptly at the ileocecal valve. Clinical features in 32 chronic cases were abdominal pain (all), diarrhea (21), fever (15; usually low-grade or irregular), wt. loss (sometimes as high as 15 kg), anemia (12), abdominal mass (11), and anorectal lesions (6). The other 9 patients in the series had acute attacks of brief duration (max. 1 wk.); pain was the major symptom (all), 8 had fever, and 6 had abdominal tenderness. All patients but 1 had 1 operation; 8 had progressive or recurrent disease and underwent more than 1 operation. Malabsorption was present in 5 of 11 patients tested; steatorrhea was found in 3. In the 6 tested patients not showing malabsorption, the lesions were restricted to the terminal ileum (less than 2 ft.), or the upper ileum. Surgery played a prominent part in treatment. In 35 instances of multiple operation, resection of the lesion was done, the short circuit was performed only 5 times. The importance of careful radiologic examination of the small intestine was emphasized.

380 GRANULOMATOUS ILEOCOLITIS. (E.) Marshak, R. H. (New York U. Sch. Med., N. Y.), A. E. Lindner and H. D. Janowitz. Gut 7(3):258-264, 1966.
Supportive medical treatment is the therapy recommended for ileocolitis (defined here as a non-specific inflammatory disease involving both the small intestine and colon) based on the results obtained with 40 patients of whom 27 underwent surgery. In 11 of these surgical cases, the disease recurred in the remaining, previously normal-appearing intestine, beginning at the anastomosis or the ileostomy stoma. The av. 5.9 yr. lapsed between the diagnosis of recurrence and the initial surgery. The mean duration of illness for the 40 patients (ages 12-45 yr.) was 9 yr. and, at the end of the follow-up period 37 patients were alive and 3 had died. The overall status of these patients, with or without surgery, was classed accordingly: excellent, 4 and 1; good, 7 and 3; fair, 12 and 7; and poor, 1 and 2, resp. The clinical features of these patients included diarrhea (only 3 cases with gross blood), abdominal cramps, fever, intraabdominal or perineal fistulae (in 50%) and abscesses. Radiological and pathological features are those of regional enteritis and granulomatous colitis; careful radiological studies enabled a diagnosis in advance of pathological confirmation. Because of the high rate of recurrence in surgical patients, steroid and other supportive therapy is preferred except for such complications as obstruction, persistent infection or prolonged disability.

381 CROHN'S DISEASE IN NORWAY, 1956-1963. (E.) Gjone, E. (Ulleval Hosp., Oslo, Norway), O. M. Orning and J. Myren. Gut 7(4):372-374, 1966.
Between 1956-1963, 156 cases of Crohn's disease were seen in Norway. The av. annual rate for this 8-yr. period was 2.6 cases/1,000,000 population; the annual rate in 1956-1960 was 2.2, compared to 3.1 cases/1,000,000 population in 1961-1963. There were no sex differences; the age range was 14-75 yr., with little variation with age in the 20-59 yr. age groups, which corresponded well to similar studies of ulcerative colitis. There was no geographical difference in incidence; the coastal northern area was similar to the rural eastern area. One main difference from ulcerative colitis was the low incidence of Crohn's disease in the young age groups: in children under 10, 1.6 at age 10-19), whereas 22 cases of ulcerative colitis were reported from pediatric departments in 1956-1960.

1391 **FRUCTOSE RESORPTION IN MAN. STUDIES ON HEREDITARY FRUCTOSE INTOLERANCE.** (Ger.) Beyreiss, K. (U. Leipzig, Germany), H. Willgerodt and H. Theile. Klin. Wschr. 44(13):787-788, 1966.

The absorption of D(-)-fructose and L(-)-sorbitose was determined in an infant with hereditary fructose intolerance; the sugars were admin. both i.v. and by continuous intragastric infusion; 24-hr. urine was analyzed, and 15-min. blood samples (100 μ l) were taken until the sugars disappeared from the circulation. Regardless of the dosage of fructose given (0.5 or 0.125 g/kg), 93-94% was absorbed; regardless of the route of admin., urinary excretion was 4.5-4.8%. In normal controls however, p.o. fructose was metabolized mostly in the intestines, and only 20-30% of the dose appeared in the circulation. In the sorbitose tolerance test (0.15 and 0.5 g/kg), the blood levels were identical after both i.v. and p.o. admin., even though the p.o. dose was 300% of the i.v. dose; only about 33% of the p.o. sorbitose was absorbed. Urinary excretion (after either route of admin.) was about 80% of the circulating sugar. The complete absorption of fructose in the intestinal tract of an infant with hereditary fructose intolerance seemed to indicate the existence of an active transport system; failure of sorbitose absorption indicated that this transport system is specific.

1392 **PRIMARY ASPECTS IN THE DIAGNOSIS OF GLIADIN INTOLERANCE. REMARKS ON 42 CASES.** (It.) Jeune, M., M. Hermier and R. Carron. Minerva Pediat. 18(11):567-571, 1966.

Background information on gliadin intolerance concerning frequency of familial allergic manifestations (3 cases), parental chronic diarrhea (3 cases), occurrence in twins (4 cases), or newborn wt. and sex (31 females, 11 males) offered little statistical information on the possible origin of the metabolic flaw. Most initial symptoms were observed at age 6-12 mo.; actual diagnosis was made at age 6-18 mo. Acute diarrhea and accompanying symptoms occurred before gliadin-containing cereals given in 10 cases; 21 infants manifested symptoms after 15 days-18 mo. of exposure to gliadin-containing cereal. The most common clinical aspect was the repeated appearance in 25 cases of a typical celiac syndrome. An increase in fecal fat was observed in 20 of 23 cases, accompanied by a distended abdomen in 26 of 36 cases, and short stature in 31 of 42 cases; osteoporosis occurred in 25 of the 37 cases tested, and steatorrhea in 19. After admin. of gliadin-free diets, immediate (within 10 days) improvement of wt., appetite and stool appearance appeared in 29 of 36 cases; height gain was apparent in 3-4 mo. It is suggested that gliadin malabsorption may be the key factor in causing common dyspeptic symptoms of early infancy.

1393 **ENZYMATIC DIGESTION OF GLIADIN: THE EFFECT OF THE RESULTANT PEPTIDES IN ADULT CELIAC DISEASE.** (E.) Bronstein, H. D. (New Jersey Coll. Med. Dent., Jersey City, N. J.), L. J. Haeffner and O. D. Kowlessar. Clin. Chim. Acta 14(2):141-155, 1966.

Gliadin was digested in a "physiological" stepwise manner: peptic, peptic-tryptic, peptic-tryptic-cotazym (cotazym contains conc. pancreatic enzymes from pancreas) and peptic-tryptic-cotazym-crude intestinal peptidase. The peptide and amino acid content of the ultrafiltrates of each digest were characterized by high voltage electrophoresis, paper chromatography, and column chromatography. The desalted peptic and peptic-tryptic digests contained a mixture of amino acids and a complex group of heterogeneous peptides. The peptic-tryptic-cotazym and peptic-tryptic-cotazym-intestinal peptidase digests were practically reduced to amino acids. Acidic fractions of the last 3 digests contained peptides which were similar to N-carboxy carboxyl peptides. Ultrafiltrates of digests 2 and 3, and the acidic peptides of the peptic-tryptic digest, produced steatorrhea in 2 patients with celiac disease. The toxicities of the peptic-tryptic acid fraction and the ultrafiltrate of the peptic-tryptic cotazym digest led to the conclusion that the acidic peptides play a major role in the toxicity of wheat protein.

- 11394 PRODUCTION IN MICE OF LOCAL TISSUE CHANGES CHARACTERISTIC OF WHIPPLE'S DISEASE BY FORMALIN FIXED SPC CELL-CONTAINING HUMAN MATERIAL. (Ger.) Müller, M. (Carl Gustav Med. Acad., Dresden, Germany) and I. Schlotterhoss. Zbl. Allg. Path. 109(1):46-51, 1966.

Tissue resected from the small intestine of a patient was fixed in 4% formaldehyde; then the mucosa was separated, and a 20% homogenate suspension was inj. into female inbred (XVII/Bl_n) mice (i.p. or s.c.; 0.3 ml/mouse). Control mice received identical material obtained from a normal person. Animals were sacrificed at 3-5-wk. interval over the next 5 mo., and preparations from s.c. and i.p. granulomas, mesenteric lymph nodes, spleen, liver, pancreas, kidneys, adrenals, lungs, and heart were examined. The periodic acid-Schiff (PAS)-positive material found in the SPC (sickleform particles containing) cells of the intestinal mucosa of the patient with Whipple's disease were freed during lysis of the inj. tissue and taken up by the epithelial cells of the granulomatous tissue formed; these cells, in turn, acquired the appearance of foam cells as a result of storage of this material, and became morphologically indistinguishable from human SPC cells in Whipple's disease. Inj. of normal intestinal mucosa produced only foreign-body granulomas without the storage phenomenon. The PAS-positive compounds stored in human SPC cells may contain a factor directly responsible for the induction of the morphological changes leading to the pathologic cell transformation.

- 11395 THE EFFECT OF INTESTINAL ANASTOMOSES ON THE INTESTINAL FLORA AND FAT ABSORPTION IN RATS. (E.) Nygaard, K. (State Hosp., Oslo, Norway). Acta Chir. Scand. Suppl. 357:306-309, 1966.

Young adult female rats underwent the following types of intestinal anastomosis: 1) resection with end-to-end anastomosis; 2) 50% bypass with side-to-side anastomosis; 3) resection with large side-to-side anastomosis; 4) bypass with end-to-side anastomosis including a self-emptying blind segment, and 5) resection with end-to-side anastomosis. Bacterial flora and fat absorption were studied; in some rats, chloramphenicol (60 mg/15 g of food) was given 3 days prior to and during balance studies. Both side-to-side and end-to-end anastomosis resulted in a marked increase in the number of bacteria distal to the anastomosis, with a shift toward coliform microbes, but end-to-end anastomosis only moderately affected bacterial flora. Side-to-side and end-to-end anastomosis also caused steatorrhea, due to abnormal bacterial flora. Changes were more pronounced when the bypassed loop was intact than when it was resected. Fecal fat excretion was normalized by chloramphenicol.

- 11396 THORACIC DUCT CANNULATION IN MAN. II. A FOLLOW-UP STUDY ON 22 PATIENTS. (E.) Werner, B. (Karolinska Inst., Stockholm, Sweden). Acta Chir. Scand. 132(1/2):93-105, 1966.

Thoracic duct cannulation was performed in 75 patients, 22 of whom were studied in a follow-up examination 1-35 mo. later. No disturbance attributed to cannulation was disclosed by routine physical examination. In testing for malabsorption, total fecal fatty acid excretion was normal in 13 of 21 subjects; in 2 patients the levels were slightly above normal limits, while 6 patients who had undergone gastric operations had steatorrhea. A D-xylose load test showed normal carbohydrate absorption in 14 of 16 cases. The radioactive triolein fecal excretion test (done on 6 patients) was normal. There were no signs of disturbed electrolyte balance, protein metabolism, liver function or the WBC picture that could not be attributed to disease. Lymphangiographic examination in 3 of 6 patients revealed a patent thoracic duct.

- 11397 DUODENAL-JEJUNAL HISTOLOGY IN MALABSORPTION SYNDROME IN INFANTS. (E.) Kuitunen, P. (U. Helsinki, Finland). Ann. Paediat. Fenn. 12(2):101-132, 1966.

Histological studies of the jejunal mucosa and clinical tests were performed in 48 infants with 1 or more symptoms (chronic or recurrent diarrhea, otherwise abnormal stools, and/or failure to gain wt.) and 7 older children with clinically diagnosed malabsorption syndrome (clinically typical celiac disease). These patients were classified into 4 groups. The malabsorption syndrome group, with

normal fecal fat and/or abnormal D-xylose excretion test (digestive failures excluded), including 10 patients showing intolerance of cows milk, 16 patients showing gluten intolerance, and 4 patients with nonspecific intolerance. Patients with a "maldigestion syndrome" included 2 patients with cystic fibrosis of the pancreas, 2 patients with primary disaccharidase defects, and 1 patient who had undergone resection of the small intestine. Three patients had an unidentified malabsorption syndrome; they were lost to follow-up before biopsies were taken. Controls included 10 infants with symptoms resembling those of malabsorption although all tests were normal, and 7 older patients (over 2 yr. old) with celiac disease, relieved by a gluten-free diet. More or less severe villous atrophy was the almost invariable finding in the infants and older children with malabsorption syndrome; the severest degree of atrophy occurred in patients with gluten intolerance. The patients with maldigestion syndrome, and those patients without any defect of absorption or digestion, usually had a normal mucosa. The mucosal atrophy usually consisted of shortening, widening and fusion of the villi, and lengthening of the crypts of Lieberkühn. The villous epithelium was flat and showed vacuolization; it was infiltrated by round cells. The lamina propria showed an increased lymphocytic infiltration. The histological findings in the small intestine showed a good correlation with the results of absorption tests. Specific treatment had a favorable effect, as reflected in the histological findings and the results of absorption tests.

398

CLINICAL AND BIOCHEMICAL OBSERVATIONS IN TWO CASES OF HARTNUP DISEASE.

(E.) Wong, P. W. K. (Royal Manchester Children's Hosp., England) and P. M. Pillai. *Arch. Dis. Child.* 41(218):383-388, 1966.

Two unrelated male children with Hartnup disease (diagnosed at age 7 mo. and 4.5 yr.) showed physical and routine laboratory findings within normal limits, except for low serum amino acid levels and persistent, marked aminoaciduria (except for proline and hydroxyproline, which were absent). Fasting L-tryptophan loading tests (100 mg/kg; i.v. and p.o. in affected children, p.o. in control subjects) were performed in these children, their clinically normal parents and siblings, and unrelated normal adults. In the affected children, the characteristic abnormalities of tryptophan metabolism (suggesting deficient intestinal transport) were seen in the basal state and after p.o. loading tests, but tryptophan metabolism was normal after the i.v. loading test. In normal adult controls, peak plasma tryptophan levels were seen 2 hr. after p.o. loading (mean 13.74 mg%), but the mothers of both patients showed a higher plasma tryptophan peak after 2 hr. than after 4 hr. (mean 9.97 and 7.33 mg%, resp.), suggesting a partial defect in tryptophan absorption. The clinically normal sister of one patient showed plasma tryptophan levels of 1.1, 2.2, and 2.6 mg%, resp., at 0, 2, and 4 hr. after p.o. loading, which also suggested impairment of tryptophan absorption. One of the affected children also showed a significant decrease in urinary 5-hydroxyindoleacetic acid after both p.o. and i.v. loading, suggesting interference with renal tubular transport of tryptophan. It is concluded that Hartnup disease is an autosomal recessive abnormality; the nature of the inhibition of tryptophan metabolism is unknown.

399

CONGENITAL α_2 - AND β -LIPOPROTEIN DEFICIENCY. (Dut.) Van Buchem, F. S. P.

(Duinroosplantsoen 15, Haarlem, Netherlands), G. Pol, J. De Gier, C. Pries and C. J. E. Böttcher. *Nederl. T. Geneesk.* 110(32):1416-1424, 1966.

Extensive studies (blood constituents, jejunal and liver histology, family histories, etc.) were done on 11 individuals showing some of the clinical symptoms of the Bassen-Kornzweig syndrome. Various other deficiencies were found in association with different degrees of α_2 - and β -lipoprotein deficiency. If β -lipoprotein was absent, or present only in traces, the Bassen-Kornzweig syndrome developed; this is always associated with steatorrhea, impaired fat absorption, accumulation of fat in the intestinal epithelium, and acanthocytosis. The deformed RBC return to normal shape when placed in normal plasma. Apparently the various changes associated with this syndrome require time for development; neurological changes in the retina, in the cerebellar tract, and cerebellum developed in later life. If 10-20% of the normal β -lipoprotein was present none of the above symptoms appeared, but the changes in the lipid pattern and the fatty acid complement were similar to those seen in the absence of β -lipoprotein. When β -lipoprotein was absent or low in

conc., there was a marked rise in the linoleic acid content of RBC and of cholesterol esters, phospholipids and triglycerides following ingestion of food with a high linolenic acid content. This β -lipoprotein deficiency is hereditary, probably associated with a recessive autosomal gene.

- 11400 A RACIAL DIFFERENCE IN INCIDENCE OF LACTASE DEFICIENCY. A SURVEY OF MILK INTOLERANCE AND LACTASE DEFICIENCY IN HEALTHY ADULT MALES. (E.) Bayless T. M. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and N. S. Rosensweig, J.A.M.A. 197(12):968-972, 1966.

Forty healthy subjects (20 Negro, 20 white) were studied. Lactose tolerance tests were performed (50 g/m² body surface); on another test day tolerance tests were done with glucose and galactose (each 25 g/m²). Proximal jejunal biopsies were obtained in 36 subjects and distal duodenal biopsies in 4. Disaccharidase assays were performed on homogenates of part of each of the mucosal biopsies obtained. Of the 21 subjects who gave a history of milk intolerance (abdominal distention, diarrhea), 19 were Negro; 20 of the 21 sensitive subjects experienced various symptoms following the lactose tolerance test. There was a significant difference in blood sugar rise between the milk tolerant and the intolerant subjects. The glucose and galactose tolerance tests did not produce symptoms. The av. intestinal lactase levels in the tolerant group were 7.1 U, compared to 1.9 U in the intolerant group. Other intestinal disaccharidase levels were similar for the 2 groups. Histologically, there was no difference between the 2 groups; in particular, the surface epithelium of the mucosa (the site of lactase activity) was intact. The data were considered to strongly favor a genetic etiology for the isolated lactase deficiencies commonly seen in adults.

- 11401 FOLATE REPLETION ASSOCIATED WITH ORAL TETRACYCLINE THERAPY IN TROPICAL SPRUE. (E.) Klipstein, F. A. (Francis Delafield Hosp., New York, N. Y.) E. A. Schenk and I. M. Samloff. *Gastroenterology* 51(3):317-332, 1966.

In 4 women with hitherto untreated tropical sprue presenting with a megaloblastic anemia secondary to combined deficiencies of folate and vitamin B₁₂, serum vitamin conc., hematologic values, intestinal absorption, and jejunal biopsy characteristics were studied before and during short-term therapy with tetracycline (1 g/day p.o.). With tetracycline therapy, serum folate returned to normal within 11 days in 3 patients; the fourth patient required supplemental therapy with physiological doses of folic acid to achieve this result. Serum vitamin B₁₂ levels were subnormal throughout the study. Tetracycline therapy also caused an initial decrease in diarrhea and improvement in the villous pattern, enzymatic activity, and morphology of the superficial epithelium of the jejunal mucosa. These changes occurred before an increase in serum folate levels or a hematologic response was noted. After evidence of folate repletion, the digestive symptoms stopped; other signs of improvement included wt. gain, partial remission of megaloblastic anemia, reversal of the abnormal pattern of lipid distribution, improvement in intestinal absorption, and further improvement of jejunal morphology. These observations suggest that p.o. tetracycline therapy causes folate repletion in some patients with tropical sprue, and that increased availability of folate results in the hematologic response. It is also suggested that certain aspects of the clinical remission and improvement of jejunal mucosa observed during tetracycline therapy are also related to folate repletion.

- 11402 EARLY DIETARY MANAGEMENT OF SUGAR INTOLERANCE IN INFANCY. (E.) Clayton, B. E. (Hosp. Sick Children, London, England), A. B. Arthur and D. E. M. Francis. *Brit. Med. J.* 2(5515):679-682, 1966.

Infant intolerance of one or more sugars is gaining increased recognition. The condition may be congenital or it may be secondary to a variety of enteropathies such as celiac disease, infections, and sprue among others. The authors describe the practical details in the management of infants requiring diets free of certain sugars. It has been found that infants intolerant of lactose are generally also intolerant of sucrose. Sucrose as well as lactose has therefore been removed from the diet. A number of different substitutes for cow's milk and breast milk have been used satisfactorily. These contain standard amounts of protein and fat (or 2/3 the standard amount of fat in the "reduced fat diet") and carbohydrate as

"liquid glucose", a syrup containing a mixture of dextrin, maltose and dextrose, or fructose with the addition of P, Ca, Na, and K. Lactase-treated breast milk is also satisfactory if virtually all the lactose is hydrolyzed. The reason for reduction of fat content is that some infants do better on a lower fat intake. It should also be noted that some individuals are sensitive to glucose; these should be tried on preparations containing fructose. It is absolutely essential that a complete vitamin supplement should be given.

- 1403 NATURE OF THE MUCOSAL CHANGES ASSOCIATED WITH MALIGNANT NEOPLASMS IN THE SMALL INTESTINE. (E.) Lee, F. D. (Western Infirm., Glasgow, Scotland). Gut 7(4):361-367, 1966.

Records and histological preparations of 18 patients with lymphoid (9 cases) or adenocarcinomatous (9 cases) malignant tumors of the small intestine were examined to determine the relationship between mucosal changes and pre-existing primary malabsorption disorders. Partial or subtotal villous atrophy (widespread mucosal changes indistinguishable from those common in primary malabsorptive disorders) was seen in 6 of the 9 cases of primary malignant lymphoid tumors; the tumors were classified as reticulosarcoma in 4 cases and lymphosarcoma in 3 cases, the remaining 2 being less readily classified. The mucosal changes ranged from abnormal surface epithelium overlying lymphoid masses in areas apart from the main tumor, to bizarre-shaped villi showing fibrous thickening of the lamina propria. In 2 patients these mucosal changes may have been related to a symptomatic, pre-existing primary malabsorption disorder. The other abnormalities probably resulted from immunological disturbances caused by the malignant tumor. These mucosal changes were less common in the closely-matched series of patients with adenocarcinoma; only 2 of 9 cases showed evidence of partial or subtotal villous atrophy.

- 1404 OCCULT NONTROPICAL SPRUE AND ASSOCIATED ATROPHIC GASTRITIS SIMULATING ADDISONIAN PERNICIOUS ANEMIA, WITH SPECIAL REFERENCE TO IMMUNOLOGIC DIAGNOSTIC STUDIES. (E.) Brown, P. (U. California, San Francisco), K. D. Wuepper and H. H. Fudenberg. Acta Med. Scand. 179(Suppl. 445): 344-348, 1966.

78-yr.-old man presented with the symptoms of Addisonian pernicious anemia, which was apparently confirmed by an abnormally low urinary excretion of vitamin B₁₂ and histamine-fast achlorhydria. However, the serum contained no antibodies to either gastric parietal cells or intrinsic factor; a Schilling test with added intrinsic factor produced no increase in vitamin B₁₂ excretion, and serum levels of both vitamin B₁₂ and folates were low. Gastric biopsy confirmed mild atrophic gastritis, while jejunal biopsy revealed subtotal villous atrophy; the primary disease was established as nontropical sprue. This case report emphasizes the value of immunological methods in distinguishing Addisonian pernicious anemia due to a genetically-determined deficiency of intrinsic factor from other forms of megaloblastic anemia.

LARGE INTESTINE

- 421 STUDIES OF THE PATHOGENESIS OF THE INTESTINAL LESIONS PRODUCED BY Citrobacter freundii. (E.) Fritz, T. E., D. V. Tolle, P. C. Brennan, J. A. Giolitto and R. J. Flynn. Argonne Nat. Lab. Ann. Rep. (ANL-7136) 1965:99-100.
- en CF#1/An1 female mice were admin. by gastric intubation viable cells of Citrobacter freundii-An1 (2×10^{13} in 0.2 ml of broth) such changes as an increased quantity of mucus in the colon and congestion of mucosa and serosa with dilation of the colon coincided with the onset of diarrhea and the appearance of microscopic lesions. Unlike previous reports, mucoid-type degeneration of the colon mucosa was not evident. The first evidence of diarrhea was observed 8 days following the infection and moderate diarrhea was evident from this time to day 18, when the condition became severe. After 20 days, diarrhea did not occur. The development of the diarrhea correlated with the colon count of C. freundii-An1. In addition, focal infiltration of the submucosa and the lamina propria with lymphocytes and plasma cells was seen in the colon 8 days after infection. From this time until day 20 these lesions became more severe, but thereafter changes were minimal or absent.
- 422 STUDIES OF THE PROTEINS OF SECRETIONS FROM TWO VILLOUS TUMORS OF THE RECTUM. (E.) Masson, P. L. (U. Clin. St.-Pierre, Louvain, Belgium), J. F. Heremans and C. Dive. Gastroenterologia (Basel) 105(5):270-282, 1966.
- The mucus secretions from two different villous tumors of the rectum showed an abundance of γ -A-type immunoglobulins. Aside from the mucins, which were not studied in detail, the A-immunoglobulins accounted for about 70% of the stainable proteins in the electrophoretic patterns on agar gel. Three minor protein components, which were apparently absent in the serum, were identified: one behaved electrophoretically as a β -globulin, whereas the other two migrated as γ^2 -globulins. The latter, one was also identified in saliva. A DEAE-cellulose column showed that the γ -A-immunoglobulins were in the range of 30%, but the discrepancy can be explained in part by the fact that the secretions contained large amounts of mucins.
- 423 A MORE PRACTICAL AND SIMPLIFIED METHOD OF COLONIC EXFOLIATIVE CYTOLOGY. A PRELIMINARY REPORT. (E.) Vacca, V. F. (Griffin Hosp., Derby, Conn.) and V. A. DeLuca, Jr. Conn. Med. 30(8):559-561, 1966.
- A practical and simplified method of colonic exfoliative cytology is described which yields readable epithelial cells in high numbers and which could be adopted for general hospital usage, as it requires the presence of a physician only for the sigmoidoscopic examination. The total time for the procedure is 1 1/2-2 hr.; rarely are more than 2 cleansing enemas required. In preparation, the patient is given a low residue diet for 2 days and a strong laxative and liquid breakfast on the day of the study. The patient is then given a cleansing enema in the Sim's position, using 1200-3500 ml of isotonic saline. By changing the position of the patient to his back and right side, the entire colon is usually cleaned. If this fluid is free of large fecal particles, the patient is then allowed to rest 1 1/2-hr. before a rubber Ewald tube is inserted via a sigmoidoscope, approx. 35 cm. In the same Sim's position, 800 ml of isotonic saline are instilled through the tube. The patient is then placed on his back and then right side, followed by a 5-min. abdominal massage. The fluid is siphoned into a beaker in ice water and the mucus is removed. Two case examples are presented; one, a 52-yr.-old woman in whom typically normal epithelial cells were found which substantiated the impression that no intrinsic disease existed in the colon, and a 80-yr.-old man in whom typically malignant cells were obtained from lesions above reach of the sigmoidoscope.
- 424 SERIOUS WATER AND ELECTROLYTE LOSS DUE TO VILLOUS ADENOMA OF THE SIGMOID RECTUM. (Ger.) Kanzler, G. (U. Munster, Germany) and J. Kort. Deutsch. Med. Wschr. 91(31):1365-1369, 1966.
- Four cases are described, 3 male, one female, age 68-77; main symptom: pseudo-diarrhea which started 1-14 yr. before admission, causing daily elimination of

LARGE INTESTINE

300-1500 ml mucous fluid (in 3-8 daily episodes), in addition to "normal" excretion. Mucous fluid was colorless and contained no traces of blood. No pains were experienced. In all 4 cases, hospital admission occurred for reasons other than the sigmoid adenomas (general debility and exhaustion in 3, mild bronchopneumonia in 1). The patients were extremely dehydrated, had azotemia (nonprotein nitrogen in 2 patients: 254 and 117 mg%, resp. Urea-N of the other 2: 134 and 80 mg%, resp.) hypochloremia (in mEq/liter: 64, 90, below 60, and 83); hypokalemia (in mEq/liter: 2.4, 3.3, 2.0, and 3.23), and hyponatremia (in mEq/liter: 104.3, 136, 120.5, and 131). The alkali reserve was normal in one case (23.5 mEq/liter), low in 2: 14.3 and 11.1, and high in one (38.6). There was no hypoproteinemia in either patient, nor abnormal electrophoretic protein patterns. Surgery was followed in all 4 cases by complete remission and restoration of the electrolyte balance. Only in one case were there indications of premalignant tissue changes in the excised polyp.

- 11425 DIVERTICULITIS COLI, WITH SPECIAL REGARD TO TREATMENT AND PROGNOSIS. (E.) Lehmann, K. (St. Lukas Stiftelsens Hosp., Hellerup, Denmark). *Acta Chir. Scand. Suppl.* 357:206-208, 1966.

The prognosis in operated and nonoperated cases was determined in 150 patients with diverticulosis of the colon (85 were over 70 yr. old). Two of the 29 operated patients and 2 of the 121 nonoperated patients died. Of 70 operated and nonoperated cases followed up for 3-19 yr., 54 died after release from the hospital, the majority of causes other than colon disease. In only 20% of the cases was the exact diagnosis of diverticulosis coli the indication for operation. The greatest risk in this illness lay in the possibility of overlooking possible carcinoma. It is concluded that milder cases have a good prognosis; in patients with more serious diverticulitis with serious complications, surgery must be performed in all patients with the slightest evidence of malignancy, and in those cases with serious infections that threaten to develop stricture, perforation, fistula or abscess.

- 11426 ACUTE APPENDICITIS WITH PNEUMOPERITONEUM. RADIOGRAPHIC DIAGNOSIS AND REPORT OF FIVE CASES. (E.) Chavez, C. M. (U. Mississippi Med. Ctr., Jackson) and B. D. Morgan. *Am. Surg.* 32(9):604-608, 1966.

Five cases of pneumoperitoneum were seen among 330 cases of acute appendicitis, 87.5% of whom were examined by abdominal X-rays; the incidence in this study was therefore 1.81%. Of 330 cases of acute appendicitis, 118 had perforation, and 40 of these also showed abscess formation. No cultures of peritoneal fluid were recorded in 38 of these patients. Bacterial culture studies were performed in 80 patients; 45 of these showed no growth; 24 grew out *Escherichia coli*, and 11 produced other miscellaneous organisms. Of the 5 cases of pneumoperitoneum, cultures were taken in 4; 1 showed no growth, and 3 grew *E. coli*. Four of these cases of acute appendicitis with pneumoperitoneum had perforation with abscess; 1 had perforation with peritonitis. It is apparent that the presence of free air in the peritoneal cavity is not related to any special form of appendicitis or to any particular pathogenic organism; the entrapped air does not influence recovery. The pneumoperitoneum may be due to the actual escape of air from the intestine, or to gas formation by bacteria within the peritoneal cavity. The presence of ileus in the cases of perforation enhanced the accumulation of air in the intestine. The resemblance of physical findings in some cases of perforated appendicitis with peritoneal irritation, to those seen in peritonitis secondary to perforation of gastroduodenal peptic ulcer, points out the importance of preoperative evaluation of such patients; the presence of pneumoperitoneum does not exclude acute peritonitis with perforation as a diagnostic possibility. The cases referred to here showed a diverse topographic distribution of air within the peritoneal cavity. The occurrence of pneumoperitoneum was unrelated to the age or sex of the patient or to the presence of a particular bacterial organism.

- 11427 ELECTRON MICROSCOPE APPEARANCES OF JUVENILE AND PEUTZ-JEGHERS POLYPS. (E.) Weller, R. O. (Guy's Hosp., London) and I. McColl. *Gut* 7(3):265-270, 1966.

Colonic polyps which had been obtained from 3 patients (ages 4, 5 and 21 yr.) with juvenile polyposis and from 1 with Peutz-Jeghers syndrome (40 yr. old) were

LARGE INTESTINE

examined under light and electron microscope as an attempt to identify features which might confirm their hamartomatous nature. No abnormal elements were demonstrated in these juvenile and Peutz-Jeghers polyps, nor were any signs of neoplasia noted. The mucosa of the polyps consisted of columnar absorptive cells and mucous secreting cells as in normal colon. The nuclei, mitochondria and other organelles all appeared normal in the epithelial cells and no abnormal cell inclusions were observed. Found in the region of the lamina propria were polymorphonuclear leukocytes, lymphocytes, plasma cells, mast cells, macrophages, capillaries, lymphatics and nerve fibers. The significance of these nerve fibers requires further investigation; however, their appearance was normal having unmyelinated axons which were similar in appearance and size range ($0.4-1\ \mu$ in diameter) to the tertiary fibers previously described in the small intestine of rats. The cellular content of the lamina propria of normal colon differed from that of the polyps in only 2 respects: the normal colon cells were more closely packed and contained more collagen.

428 SIGMOID DIVERTICULITIS. EVALUATION OF CURRENT PRACTICE IN A COMMUNITY HOSPITAL. (E.) Moseley, R. V. (Peter Bent Brigham Hosp., Boston, Mass.) and F. P. Ross. Ann. Surg. 164(2):275-283, 1966.

151 patients who received medical treatment for diverticulitis, 76 developed significant recurrences of whom 3 died, 56 required operation and 17 again responded to medical treatment. From the period of 1954-1963, a total of 85 patients were treated surgically at this community hospital. A predominance of male patients was seen in the younger age groups and only 1 death occurred under the age of 70 yr. The principal indication for primary resection (48 were performed) was recurrent colonic symptoms. Of these operations, 12 were conducted during an attack and resulted in a high morbidity (8) rate and 1 death. When the primary resection was done later, the morbidity was low (2) with 1 death. The principal indications for stage surgery were severe inflammation (with or without perforation) and fistula formation. In the 22 completed cases (10 cases did not return for the second stage), 9 showed morbidity and 4 died. Of the total 77 patients who survived colon resection, 14 died subsequently, but in no instance could death be attributed to diverticular disease. The remaining 62 patients have been followed for an av. of 7 yr. and 84% of them are asymptomatic. Only 1 of the 10 complaints was attributable to recurrent diverticulitis. This rate of recurrence is far less than that found in the group which received only medical treatment, which exemplifies the importance of early elective surgery. The incidence of colon carcinoma was no greater in this group than in the general population. Patients with hypertension and peripheral vascular disease showed a greater tendency for rectal bleeding.

429 ISCHAEMIA OF THE COLON: AN EXPERIMENTAL STUDY. (E.) De Villiers, D. R. (U. Cape Town, South Africa). Brit. J. Surg. 53(6):497-503, 1966.

When a segment of dogs' descending colon was isolated from the circulation for 4 hr. and perfused with Tyrode soln., the initial response was gross submucosal inflammatory congestion and edema associated with variable mucosal destruction due to the acute membranous inflammation with resultant ulceration. Thirty days after the ischemia had been induced, mucosal regeneration was complete and the inflammatory reaction seen in the mesocolic adipose tissue had totally subsided. However, as the mucosa was returning to normal, the submucosal and serosal pathology progressed to eventual fibrosis with marked thickening of these strata. The experimental colon segment was found to have shortened to 1/3 or 1/2 of its original length and this area uniform narrowing of the bowel caliber was obvious (100-268 days after the temporary isolation). On palpation the colon felt hard, with definite thickening of the wall: lumen stenosis was confirmed at autopsy. Of the 18 dogs used, 7 died within 48 hr. of the operation from complete gangrenous necrosis with free perforation and generalized peritonitis. Throughout these experiments, the intramural ganglion cells were consistently present in adequate numbers and of normal structure in both submucosal and myenteric plexuses which would tend to dismiss ischemia as a possible factor in the genesis of congenital aganglionosis.

LARGE INTESTINE

- 11430 THE ROLE OF ERYTHRASMA IN PRURITUS ANI. (E.) Bowyer, A. (Guy's Hosp., London) and I. McColl. Lancet 2(7463):572-573, 1966.

Of 32 patients with intractable pruritus ani, 4 were found to have erythrasma, formerly regarded as a fungal infection, but now known to be caused by Corynebacterium minutissimum, a gram-positive organism producing a red porphyrin fluorescence under UV. The infected skin shows a very striking coral or salmon-pink fluorescence when irradiated with UV. In 1 of the 4 cases, the UV lamp produced a coral fluorescence of the perianal skin, the umbilical and unguinal regions and between toes 4 and 5 of both feet; 2 of the patients had brilliant fluorescence of the perianal skin and between toes 4 and 5 of both feet; the fourth patient showed coral pink fluorescence of the perianal skin, the groins and all the toe webs of both feet. All 4 patients were treated with erythromycin (250 mg every 6 hr. orally) for 2 wk., half-strength white field's ointment to the toe webs, and betamethasone lotion to the perianal skin. All patients were freed of symptoms within 2 wk. There was some tendency to relapse when the perianal skin again became fluorescent. Further courses of erythromycin always produced rapid and complete relief of symptoms.

- 11431 PERSONALITY AND THE VERMIFORM APPENDIX. (E.) Murphy, H. B. M. (McGill U., Montreal, Quebec, Canada). J. Health Hum. Behav. 7(3):153-162, 1966

Students at a Singapore and a Montreal university showed an association between choice of a career and history of appendectomy. One of 230 science, engineering, architecture students in Singapore had undergone appendectomy compared with 107 of 778 such students in Montreal. Seven of 288 Singapore liberal arts students had undergone appendectomy compared with 21 of 101 Montreal students. The highest incidences were seen in medicine and dentistry students, 19 of 478 in Singapore and 15 of 65 in Montreal. Female students of the various groups and the 2 countries showed similar differences. These differences were beyond chance expectation. A careful analysis of the Singapore data indicated that the incidence was not linked to body build or ethnic type, frequency of illness, accidents, age, academic level, use of medical services, errors in reporting, emotional instability, social class or westernization. Rorschach and Sentence Completion tests indicated that incidence was related to concepts of the self and parents. The medical orientation is more feminine or maternal, the scientific orientation being related to strength and conquest. The first group were more closely identified with their mothers, the latter with their fathers.

- 11432 RESPONSE OF THE SIGMOID COLON TO METHACHOLINE STIMULATION IN PATIENTS WITH THE CHRONIC FORM OF CHAGAS' DISEASE. (Por.) Vieira, C. B. (U. San Paulo), R. Alves de Godoy, U. G. Meneghelli and C. F. Carril. Arg. Gastroent. 3(1):21-26, 1966.

Approx. 12 hr. after intestinal lavage, 10 patients with Chagas' disease who were either asymptomatic or suffering minimal distress and 10 with demonstrable megaesophagus received methacholine, 0.05 mg/kg as a 1% soln., i.m., in a kymographic study of the tonus and contractile responses of the sigmoid colon, employing a balloon which was introduced by means of a rectosigmoidoscope. None of the patients had megacolon, although all showed positive complement-fixation tests to Trypanosoma cruzi. In 6 normal subjects who served as controls, medication had no effect or had a mildly depressive effect on sigmoidal contractions and tonus. In 3 of the 20 patients studied (1 of 3 asymptomatic; 2 of 3 with megaesophagus), medication intensified sigmoidal tonus and increased both the amplitude and the force of contractions significantly, appearing to confirm a pre-ectasic blockage or denervation of the sigmoid resulting from degenerative lesions of the intramural plexus of Auerbach.

Ulcerative Colitis

- 11506 PLASMA PHOSPHOLIPIDS IN ULCERATIVE COLITIS: A QUANTITATIVE THIN LAYER CHROMATOGRAPHIC STUDY. (E.) Gjone, E. (U. Clin. State Hosp., Oslo, Norway). Scand. J. Clin. Lab. Invest. 18(3):263-267, 1966.

When individual plasma phospholipids were studied quantitatively by means of thin-layer chromatography in blood drawn (after overnight fasting) from 12 patients with ulcerative colitis, a rise in plasma lysolecithin was not seen in any patients. Low total plasma phospholipids with an absolute and relative decrease of lysolecithin was found in 8 patients who had ulcerative colitis with total colonic involvement in a phase of fulminant chronic colitis. Normal plasma phospholipid pattern was encountered in 4 patients, of whom 3 had proctitis or quiescent chronic segmental colitis. The age of the patients ranged from 15-66 yr. and the symptoms had existed anywhere from 2 mo. to 13 yr. Signs of liver damage were not observed in any patients. This hypolysolecithinemia may be related both to reduced formation, or, to increased acylation to lecithin.

- 11507 MORPHOLOGICAL CHANGES OF THE COLON MUCOSA IN NONSPECIFIC ULCERATIVE COLITIS ACCORDING TO ASPIRATION BIOPSY DATA. (Rus.) Zabelina, T. N. (Inst. Med. Res., Leningrad, USSR). Ter. Arkh. 38(5):86-92, 1966.

Biopsy specimens from 67 patients with chronic nonspecific ulcerative colitis of 1 mo.-over 10 yr. duration were examined. The most characteristic changes seen in the acute stage were in the colon epithelium and consisted of profuse cellular infiltration, stasis, changes in the vascular epithelium, and foci of secondary infection in the crypts. During quiescent stages, the epithelium regenerated rapidly, with the tectorial epithelium depressed or normal. Beaker-like cells appeared in the crypts in an irregular pattern; cellular infiltration was reduced, and connective tissue developed in the submucosa. During remission, the mucous membranes were smaller and all the mucosal layers were united by connective tissue. The beaker-like cells in the crypts were more numerous, and were also seen in the tectorial epithelium. Cellular infiltration was slight. Deformed and cyst-forming crypts were also noted.

- 11508 SURGICAL PROGRESS IN THE MANAGEMENT OF CHRONIC ULCERATIVE COLITIS. (E.) Judd, E. S. (Mayo Clin., Rochester, Minn.). Surgery 60(4):783-789, 1966.

Surgical progress in chronic ulcerative colitis is reviewed. Use of steroids must be carefully considered, since these agents can present even more complex problems, and cancer secondary to ulcerative colitis demands an entirely separate consideration. A one-stage removal of the entire colon and rectum eliminates the disease; if done at the proper time, following suitable preparation, the risk is low and results are compatible with virtually complete rehabilitation. Indications requiring more current emphasis, including intractability, cholestatic hepatic disease, malignant change, and developmental retardation, are discussed.

- 11509 STUDY OF BIOLOGICAL DISTURBANCES OF ULCERO-HEMORRHAGIC RECTOCOLITIS. (Fr.) Bouvry, M. (Bichat Hosp., Paris). Vie Med. 47(Ser. E):779-794, 1966.

Fifty-nine of 62 determinations showed red blood cell count below 4 million; 34 of these were below 3.5 million and 19 under 3 million. Serum iron was found to be between 30 and 75 $\mu\text{g/liter}$. The total protein was 72.7 g/liter in distal forms and 59.3 g/liter in diffuse types coinciding with levels previously reported. Albumin levels registered approx. 26.7 g/liter in the 53 diffuse forms while gamma globulins increased variably between 2.2 to 30.1 g/liter against a norm of 9 to 13 g/liter. Increased loss of water was a constant danger to these patients. Sodium loss varied from 72 mEq to 300 mEq in a few serious cases as compared to a normal 5 mEq loss. The colon appeared less effective in sodium absorption, retaining less than 40%. Flame photometric studies showed plasma sodium to be reduced (131 as compared to a normal 142 mEq) in patients with ulcerative colitis. Sodium diffusion was augmented in these patients. Daily potassium fecal losses were 26.7 mEq as compared to 8-16 mEq. Urinary losses were increased, especially in serious cases, and blood potassium varied from a normal of 4-5 mEq/liter to 4.3 mEq/liter in distal forms to 3.7 mEq/liter in diffuse types.

1510 SIGMOIDOSCOPY AND CYTOLOGY IN THE DETECTION OF MICROSCOPIC DISEASE OF THE RECTAL MUCOSA IN ULCERATIVE COLITIS. (E.) Watts, J. McK. (Gen. Infirm., Leeds, England), H. Thompson and J. C. Goligher. Gut 7(3):288-297, 1966.

When results obtained by sigmoidoscopy and cytological analysis of rectal mucosal secretion were compared with those obtained by a rectal mucous membrane biopsy, the cytological technic was considered slightly more reliable as abnormal exfoliative cytologic findings were reported in 92% of those cases with definitely abnormal biopsies (there were 2 false positive cases). An overall sigmoidoscopic assessment of abnormal occurred in 93% of those with abnormal biopsies, but this was also reported in 17% of those with normal biopsies. This same danger of false positives arose when either loss of vascular pattern or contact bleeding was used as the single criterion at sigmoidoscopy. The most reliable criterion in this technic seemed to be loss of vascular pattern combined with contact bleeding which was recorded in 75% of those cases with abnormal biopsies and, more importantly, did not occur in any with normal biopsies. This comparison of these 3 technics for diagnosing ulcerative colitis demonstrates that a rectal biopsy is indicated in any patient with a history suggestive of colitis, having normal or equivocal sigmoidoscopic appearances in the rectal mucosa.

1511 PERSISTENCE OF MUCOSAL ABNORMALITY IN ULCERATIVE COLITIS. (E.) Dick, A. P. (Addenbrooke's Hosp., Cambridge, England), L. P. Holt and E. R. Dalton. Gut 7(4):355-360, 1966.

An unselected series of 200 cases of ulcerative colitis followed up from 5-14 yr. were resurveyed; 29 of these patients had died and 22 were undergoing further surgical treatment. Of the remaining 149, 113 were examined by sigmoidoscopy and had mucosal biopsy performed. The histological examination of specimens from 79 patients free of symptoms revealed abnormalities in 71. Of the 8 symptom-free patients with normal histology, sigmoidoscopy was considered normal in 5 and abnormal in 3. Of 34 patients still having symptoms, the histology of the mucosa in 32 was abnormal. The abnormalities comprised: (1) Abnormal glandular pattern, i.e. irregularity in size and shape with a tendency to enlargement of gland and lumen with branching and forking, was frequent. Excess chronic inflammatory cells occurred in many in the quiescent phase with excessive round cells and plasma cells in the lamina propria and around the glands. (2) The presence of polymorphonuclear leukocytes is always abnormal. The sigmoidoscopic examination often showed abnormalities of the mucosa in individuals showing no symptoms. It is concluded that in the vast majority of patients with colitis, once the disease has developed, the mucosa remains permanently abnormal whether symptoms are present or not, a fact which may be related to the tendency to relapse and to increased tendency to carcinoma of the colon.

1512 DANGERS OF IMMUNOSUPPRESSIVE DRUGS IN ULCERATIVE COLITIS. (E.) Bean, R. H. D. (Repatriation Gen. Hosp., Heidelberg, Victoria, Australia). Brit. Med. J. 2(5509):361, 1966.

In the treatment of ulcerative colitis with azathioprine the author considers that the same principles apply as in the use of 6-mercaptopurine (M). He considers it important that the initial dose be the max. tolerated dose and that reduction or cessation of therapy depends upon whether success or failure follows the initial dose. To increase dosage after failure of inadequate therapy is extremely hazardous. He has been using large intermittent doses of M for 18 mo. These are often given in conditions in which the marrow is extensively involved, as in acute myeloid leukemia and carcinomatosis; neutropenia is seldom severe, although total doses of M in excess of 20 g over 6-12 mo. are not uncommon. As a principle, care should be exercised in the use of antimetabolites when the patient has been recently or is being treated with a drug which is a marrow depressant or in the presence of neutropenia. Antimetabolites remain a crude method of combating ulcerative colitis. Initially the author admin. 0.5 to 1.0 g of M and 100 mg of hydrocortisone depending upon the physical condition of the patient, and acuteness of the disease. The response is evaluated over 2-3 days and therapy repeated every 3-7 days. It is unusual to require more than 2 or 3 large doses of M. As soon as definite improvement occurs, the dosage is reduced to 0.25 g of M with 40 mg of hydrocortisone

LARGE INTESTINE

Ulcerative Colitis

every 2 or 3 days; when improvement is stabilized 100 mg of busulfan are given over 4 days. The M is stopped 14 days after the course of busulfan is completed. Long remissions occur with this regimen.

- 11513 RESULTS OF AND INDICATIONS FOR PREFRONTAL SURGERY IN HEMORRHAGIC RECTOCOLITIS. (Fr.)(Rev.) Carasso, R. Vie Med. 47(Ser. E):761-766, 1966.
A review of 50 cases reported in the literature concludes that prefrontal electrocoagulation led to favorable results in 80% of the patients with hemorrhagic rectocolitis who were treated within 2 yr. of the onset of symptoms, 55% of those who were treated within 2-5 yr. and less than 50% of those treated after more than 5 yr. of illness. In responding patients, results included abrupt termination of pain, hemorrhaging and diarrhea; healing of ulcerations; diminution of mucosal fragility and granulation of the rectal mucosa, similar to that which is seen in spontaneous remissions. The progressive diminution of effectiveness as duration of illness was prolonged was attributed to such irreversible changes as chronic inflammatory pseudopolypoidosis and diffuse, stenosing sclerosis or scleriform lipomatosis of the colon and rectum. However, even in advanced cases which were continuing to hemorrhage, the intervention stopped pain and bleeding, with improvement of general status within a few wk. and enhancement of the effects of subsequent colectomy. The technic was considered contraindicated for patients responsive to medical treatment and for those with advanced stages of the disorder which were no longer characterized by extensive bleeding.

EXOCRINE PANCREAS

- 1522 MUCOPOLYSACCHARIDE FROM PATIENTS WITH CYSTIC FIBROSIS OF THE PANCREAS. (E.) Lowe, C. U. (State U. New York. Med. Sch., Buffalo), W. Adler, O. Broberger, J. Walsh and E. Neter. *Science* 153(3740):1124-1125, 1966.
- Immunologic and physical technics led to the isolation of an apparently unique glycoprotein in stools of patients with cystic fibrosis of the pancreas. The product obtained by dialysis and lyophilization of the acid hydrolysate of polysaccharide was designated CHO-I; it was prepared individually from 50 cystic fibrosis patients (with polysaccharide (CHO-I-C) patients and from 25 healthy controls (CHO-I-N), and antisera against each were prepared in rabbits. When antisera against CHO-I-C were absorbed with CHO-I-N, a precipitin band still occurred when tested against CHO-I-C; the reaction with CHO-I-N was completely abolished however, which indicates a unique antigen in CHO-I-C. A distinct difference in composition between the 2 polysaccharides was shown with molecular sieving, continuous-flow electrophoresis, equilibrium-gradient centrifugation. When biopsy specimens of rectal mucosa from cystic fibrosis patients were first treated with rabbit antiserum to CHO-I-C and then with fluorescein-labeled antiserum to rabbit γ -globulin, immunofluorescence located the unique glycoprotein in the cytoplasm of epithelial cells. This glycoprotein had a molecular wt. exceeding 1 million. The intrinsic structure of the mucopolysaccharide probably included amino acids in addition to carbohydrates.
- 1523 LATENT MUCOVISCIDOSIS IN ADULT DIABETICS. (STATISTICAL CONTRIBUTION AND SOCIAL CONSIDERATIONS.) (It.) Proto, R. (U. Bari, Italy), G. Nardelli and R. Giorgino. *Acta Diabet. Lat.* 2(3):350-357, 1966.
- When Knight's sweat test was admin. to a group of adult diabetics after 3 mo. of a hypocaloric diet without restriction as to fluid intake, 25 of 200 showed 3+ or 4+ imprint scores and 18 of the 25 had sodium conc. of more than 80 mEq/liter in the sweat. Comparable tabulations among a group of control non-diabetic patients were of 163 and 5 of 8, resp. Following admin. of deoxycorticosterone acetate (20 mg m., single dose), sodium conc. in the sweat was still in excess of 80 mEq/liter in all 18 diabetic patients and in 3 of the 5 non-diabetic patients with initially high values. In some of the diabetic patients, the sodium conc. actually increased after treatment, although similar treatment is known to reduce sweat sodium conc. by 20-40% in normal subjects. This maintenance or increase of sodium conc., which is characteristic of mucoviscidosis, may indicate a possible relationship between that disorder and diabetes mellitus.
- 1524 EXOCRINE ACTIVITY OF THE PANCREAS IN CHOLELITHIASIS. (Rus.) Kotiger, Ia. S. (Belts Rep. Hosp., Moldavian SSR). *Klin. Med. (Moskva)* 44(6): 34-39, 1966.
- Disturbances in exocrine pancreatic function were seen in 39 of 76 patients operated for cholelithiasis, including all 8 patients with biliopancreatic reflux. Hyperension of the ampulla of Vater (present in 12 cases) was associated with disturbances of exocrine pancreatic function in 6 of 8 patients with spastic disorders of the sphincter, 3 of 3 patients with stenosing papillitis, and 1 patient with a anometric and X-ray picture of hypertension of the ampulla of Vater; therefore, disturbances in pancreatic juice passage through the ampulla of Vater led to exocrine pancreatic disturbances in 10 of 12 cases. Exocrine pancreatic disturbances were also seen in 19 of 54 patients with normal ampullary function. Four case histories are given.
- 1525 ROLE OF GASTROENTEROSTOMY IN MANAGEMENT OF PANCREATIC CARCINOMA. RISK OF DUODENAL OBSTRUCTION AFTER BILIARY BYPASS. (E.) Glantz, G. (U. California Sch. Med., Los Angeles) and R. S. Ozeran. *Am. Surg.* 32(10): 670-672, 1966.
- The records of 154 patients with adenocarcinoma of the pancreas seen from 1950-1960 are reviewed; 51 were not operated on, but 103 underwent a variety of surgical procedures. These surgical procedures, together with operative mortality, were as follows: biliary decompression with gastroenterostomy, 3 of 24 (13%); biliary decompression without gastroenterostomy, 12 of 34 (34%); enterostomy 0 of 3; pancreaticoduodenectomy, 0 of 7; and exploration with biopsy 7 of 35 (20%).

EXOCRINE PANCREAS

The av. survival times in these groups were 5.0, 5.8, 2.7, 15.0 (range 2-36), and 3.6 mo., resp. Duodenal obstruction developed in 50% of the 22 patients who survived biliary decompression without gastroenterostomy. It is suggested that combination of gastroenterostomy with some form of internal biliary decompression will give max. palliation to the majority of patients treated for pancreatic carcinoma.

- 11526 REDUCTION IN CARDIOVASCULAR AND METABOLIC RESPONSES TO PHENYLEPHRINE IN ACUTELY PANCREATECTOMIZED DOGS. (E.) Goldberg, E. (Albany Med. Coll., Albany, N. Y.) and I. Rosenblum. Am. Heart J. 72(4):482-488, 1966.

Pancreatectomy reduced the rise in systolic pressure, myocardial contractile force, plasma glucose, and heart rate produced by infusion of the largest dose of phenylephrine (1-10 μ g/kg/min.). Pancreatectomy, however, did not alter the responses to infusion of isoproterenol. Partial restoration of the pressor response to phenylephrine in pancreatectomized dogs was seen after addition of insulin (2 U/kg) to the infusion mixture. These results may indicate a role for insulin in facilitating the response to sympathomimetic amines.

- 11527 THE USE OF 2-METHYLCYANOACRYLATE IN DESTRUCTIVE SURGERY OF THE PANCREAS. (It.) Peracchia, A. (U. Modena, Italy), G. P. Deriu, M. Fontanili and F. Belbusti. Chir. Pat. Sper. 13(3-4):75-90, 1965.

In mongrel dogs subjected to amputation of the splenic process of the pancreas, topical application of 2-methylcyanoacrylate (Eastman 910) to the surface of the wound was followed by a clearly localized, inflammatory process with subsequent encapsulation and gradual resorption of the resin, postoperative retention of pancreatic fluid and an absence of postoperative complications. Control animals exhibited considerable loss of pancreatic fluid, pseudocyst formation, pancreatic fistulae, steatonecrosis extending to the omentum or throughout the peritoneum and significant evidence of postoperative autodigestion. It is suggested that the technic may be suitable for use with human patients.

- 11528 MORPHOLOGICAL AND FUNCTIONAL STUDIES OF THE EXOCRINE PANCREAS IN CERTAIN DIETETIC CONDITIONS. (EXPERIMENTAL STUDY.) (It.) Gasbarrini, G. (U. Bologna, Italy), F. Faggioli and G. Fontana. Arch. Pat. Clin. Med. 42(4):271-319, 1966.

In male, albino Sprague-Dawley rats, electron microscopic studies of exocrine pancreatic tissue after 6-10 days of various types of unbalanced diet showed ultrastructural changes corresponding in varying degrees to changes of the endocrine content of the tissues examined. The conc. of mucinoid granules was increased in the acinic cells following a high protein diet or resumption of a balanced diet after maintenance on one of the others under study; was sharply decreased after high lipid or high lipid plus high carbohydrate diet, with zymogenic degranulation observed in animals with increased carbohydrate intake. All of the unbalanced diets tended to induce mitochondrial hypertrophy, which was particularly marked after a high lipid or high lipid plus high carbohydrate diet. The cristae were decreased in number by a high lipid diet; markedly increased by increased carbohydrate intake; somewhat increased and discernibly elongated by a high protein or high protein plus high carbohydrate diet. After a high lipid or high lipid plus high carbohydrate diet, the canaliculi of the endoplasmic reticulum were dilated. The Golgi apparatus and the nucleoli were rendered hypertrophic by a high protein diet but were essentially atrophic following a high lipid diet, which also induced conc. of lipid materials in the acinic cells, varying in direct proportion to the duration of the diet. This conc. of lipids was the only morphologic change which was not spontaneously reversible within 10 days of resumption of a normally balanced diet. A high lipid diet reduced tissue lipase, trypsin and amylase; a high protein diet reduced amylase but increased trypsin; a high carbohydrate diet increased amylase but decreased trypsin and lipase. Lipase was diminished by a high lipid plus high protein or high lipid plus high carbohydrate diet; amylase was diminished by increased lipid plus increased protein intake but slightly increased by the high protein plus high carbohydrate diet.

EXOCRINE PANCREAS

- 11529 ENDOCRINOPATHY ASSOCIATED WITH PANCREATIC CARCINOMAS. REVIEW OF HOST FACTORS INCLUDING HYPERPLASIA AND GONADOTROPIC ACTIVITY. (E.) Soloway, H. B. (Columbia U., New York) and S. C. Sommers. Ann. Surg. 164(2): 300-304, 1966.

The percentage of non-cancerous endocrine abnormalities found in 120 autopsied cases of pancreatic duct cell carcinoma as compared to 120 non-cancer controls (who were matched according to age and sex) were as follows: in the 47 females, ovarian cortical stromal hyperplasia, 64% as compared to 41%, endometrial hyperplasia, 33% as compared to 13% and uteri with myomata 30% as compared to 11%; in the 73 males, prostatic hyperplasia and prostatic atrophy were only slightly greater in the cancer group. Malignant extrapancreatic tumors were observed in 23.3% of the patients with pancreatic duct cell carcinoma. Among the women the predilection of these tumors for the secondary sex organs, and the high incidence of ovarian cortical stromal and endometrial hyperplasia, suggests that excessive gonadotropic and, secondarily, estrogen stimulation occurs with this type of cancer in women only as among men the incidence of prostatic cancer was within the expected range for middle-aged men. Diabetes mellitus and thyroid neoplasms were common in both the male and female group with pancreatic cancer, while their adrenals were essentially similar to those of the control group.

- 11530 ANGIOGRAPHIC VISUALIZATION OF THE SECRETIN-STIMULATED PANCREAS. (E.) Taylor, D. A. (Columbia U. Coll. Phys. Surg., New York, N. Y.), K. L. Macken and A. S. Fiore. Radiology 87(3):525-526, 1966.

Premedication for this test was 50 mg meperidine HCl and 50 mg promazine HCl. The stomach was outlined by a combination of endo- and perigastric gas according to the technic of Frimann-Dahl. After percutaneous transfemoral passage of a catheter into the celiac and/or superior mesenteric arteries, 150 U of secretin was inj. into the catheter; 2 or 3 min. later arteriography was performed using 40 ml diatrizoate methylglutamine, an inj. pressure of 75-100 pounds/inch² and filming rates of 2/second for 5 seconds and 1.5/seconds for a total of 26 films. Three patients have been examined by this technic. No untoward reactions were observed. The figures show the excellent delineation of the pancreatic vasculature realizable in arteriography when the examination is preceded by admin. of secretin.

- 11531 FECAL ENZYME ASSAY AS AN AID TO THE DIAGNOSIS OF PANCREATIC EXOCRINE INSUFFICIENCY. (E.) Wilding, P. (Gen. Hosp., Birmingham, England), J. G. Banwell and W. T. Cooke. Am. J. Dig. Dis. 11(9):722-727, 1966.

The levels of trypsin and chymotrypsin in the feces of 100 patients with various gastrointestinal disorders were determined in order to investigate further the possible diagnostic value of these measurements. Total 24-hr. samples of stool were homogenized with 0.9% NaCl, the vol. of which never exceeded in wt. the wt. of the stool. Enzyme assays were performed using an automatic titrator with 0.005 N NaOH; titrations were done in duplicate with excellent reproducibility. Standard enzyme soln. were prepared from crystalline enzymes to determine standard curves for these enzymes. Control subjects were 4 members of the hospital staff. The results showed no correlation between enzymatic conc. in the feces and any gastrointestinal disorders including those of the pancreas.

- 11553 ACUTE PANCREATITIS DUE TO Clonorchis sinensis. (E.) McFadzean, A. J. S. (Queen Mary Hosp., Hong Kong) and R. T. T. Yeung. Trans. Roy. Soc. Trop. Med. Hyg. 60(4):466-470, 1966.

Ova of Clonorchis sinensis were found in either the duodenal fluid (in 83 of 89 patients so tested) or the feces (in 7 of 21 patients) in 91 of 110 southern Chinese suffering from acute pancreatitis of undetermined etiology. With 75% of these patients, the attack occurred 1-3 hr. after the consumption of a meal which was unusually high in protein of animal origin, and in wine. Evidence was present that the adult flukes resided not only in the bile ducts but also in the pancreatic ducts causing obstruction and producing secondary changes in the duct walls which included metaplasia of the epithelium. In the presence of the obstruction caused by the fluke per se, plus these secondary changes in the pancreatic duct walls, apparently the pancreatic juice secretion stimulated by the unusually high-protein meal precipitated pancreatitis. The mean age of the patients was 37 yr.; and the ratio of males to females was 3:2. The established incidence of C. sinensis infection in this group is double that encountered in a random sample of the population and, in view of the methods of diagnosis employed, the infection rate in this group was probably actually higher.

- 11554 THE CLASSIFICATION OF PANCREATITIS. (Ger.) Güzlow, M. (U. Rostock, Germany). Deutsch. Zschr. Verdau. Stoffwechselkr. 26(1):3-11, 1966.

An analysis of 901 cases of pancreatitis studied over the past 15 yr. (representing 1.5% of a total hospital population of 60,000 for that time span) was made in an attempt to classify them into groups according to morphology, etiology, or clinical considerations. The symptomatology of acute and chronic forms of the disease are given, together with the author's definitions of mild to moderately severe, severe, and very severe pancreatitis. There were 208 cases of severe to extreme acute pancreatitis (18 confirmations by surgery, 89 by autopsy); 67% of these were women; 61% had biliary calculi; 34% of survivors with calculi underwent cholecystectomy. Moderately severe acute disease was seen in 299 cases; 74% were women, 69% had calculi, and 40% of survivors of the latter group underwent cholecystectomy as above. Recurring, mainly painful forms of pancreatitis were seen in 155 cases; 70% were women, 55% had calculi, and 42% of survivors underwent cholecystectomy. Chronic forms, mainly secretory and digestive insufficiencies, were seen in 239 cases. Forty-nine per cent were women, 39% had calculi, and 50% of survivors underwent surgery. Of the entire group, 65% were women, and 57% had gallstones. Of 615 patients admitted with an acute biliary attack over a 3-yr. period, 362 (76% were women) had calculi without pancreatitis, 122 (70% were women) had calculi and pancreatitis, and 130 (50% were women) had pancreatitis without calculi. There were also 17 patients (12 were women) with pseudocysts (2 traumatic, 15 postnecrotic), of whom 7 had gallstones, and 18 other cases of pancreas calcification (6 were women). Among the possible etiologic factors the most frequent was biliary calculi (57% or 484 cases), recurring ulcer (9% or 82 cases), diabetes (6.5% or 59 cases), previous infection (6.3% or 57 cases), simultaneous liver disease (4% or 36 cases), alcoholism (3% or 28 cases), duodenal diverticulosis (1.7% or 16 cases), necrotic foci and abscesses (1.7% or 15 cases), postoperative pancreatitis (1.3% or 12 cases), pregnancy (2.3% or 21 cases), and several other possible factors of less than 1% frequency each. It is concluded that, except for diseases of the biliary tract, no other specific etiologic factors can be postulated in the group studied.

- 11555 DETERMINATION AND CLINICAL SIGNIFICANCE OF SERUM LIPASE. (E.) Roe, J. H. (George Washington U. Sch. Med., Washington, D. C.), H. E. Tickin and M. Schneider. Enzym. Biol. Clin. (Basel) 7(1/2):73-77, 1966.

The mean serum lipase value for 42 normal subjects was 4.5 ± 2.7 U; the normal range was 1-10 U within 95% confidence limits. In acute pancreatitis, the serum lipase increased significantly in all cases; the serum lipase and serum amylase conc. paralleled each other during all phases of the disease. Serum amylase was elevated in 2 patients with acute inflammation of the salivary glands, but no

increase in serum lipase activity was seen. There was no consistent pattern of change in the serum enzymes in 16 patients with liver disease, or in 10 cases of carcinoma of the pancreas (some with liver metastases). There was no apparent relationship between renal disease and serum conc. of these enzymes. The i.v. admin. of heparin (5000 U) to 10 fasting human subjects was followed in 10 min. by a sharp increase (av. 154%) in the serum lipase level; these results agree with observation on lipoprotein lipase made by many investigators.

- 11556 EXOCRINE AND ENDOCRINE PANCREATIC FUNCTION IN DIABETES MELLITUS AND CHRONIC PANCREATITIS. (E.) Peters, N. (Addenbrooke's Hosp., Cambridge, England), A. P. Dick, C. N. Hales, D. H. Orrell and H. Sarnar. Gut 7(3):277-281, 1966.

The study of endocrine and exocrine pancreatic function in 5 patients (aged from 55-80 yr.) with chronic pancreatitis showed no direct relationship between the degree of disturbance of these two parameters. These patients showed a limited ability to secrete an alkaline, enzyme-rich pancreatic juice, either at rest or following stimulation with secretin or pancreozymin, yet the mean vol. of pancreatic juice did not differ from that of the control group or from that obtained from a diabetic group. According to the definition of mild diabetes as being a failure of the blood glucose to fall below 140 mg% 1 and 1/2 hr. after an oral glucose load of 50 g, all these chronic pancreatitis patients were mildly diabetic. The mean fasting insulin conc. for this group was normal, but they failed to respond to a glucose load. In contrast, those 5 patients (aged from 58-79 yr.) with mild diabetes mellitus were able to increase their output of insulin in response to a glucose load even though the abnormal glucose tolerance curve indicated that this insulin was ineffective. In this group, the mean insulin curve showed a high fasting conc. with a delayed rise and a failure of the insulin level to return to normal after the glucose loading. In these patients, the exocrine pancreatic function was normal in response to secretin and pancreozymin stimulation.

- 11557 PROXIMAL DUODENAL DEFORMITIES DUE TO PANCREATITIS. (E.) Farman, J. (Groote Schuur Hosp., Cape Town, South Africa), L. Werbeloff, I. N. Marks, S. Bank and J. H. Louw. Brit. J. Radiol. 39(465):662-668, 1966.

Two main types of deformities were noted in 111 patients with calcific (51) and non-calcific (60) pancreatitis; the first (35 cases) resulted from pancreatic swelling or enlargement, and the second (12 cases) was caused by cicatrization and adhesion formation from pancreatic inflammation. Normal duodenal caps were found in 58 of the patients. The first type of deformities consisted of filling anomalies, such as a "target" type consisting of a rounded filling with a central barium core (12 patients), a 0.5-1.0-cm rounded filling associated with extrinsic cap compression (6 patients), or compression-caused cap deformity (17 patients). These filling defects may be due to the encroachment of the enlarged head of the pancreas above or below the cap and may be a transient manifestation of an acute flare-up. The "target" deformity may be due to a puckering of the mucosa. The other deformities strongly resembled those due to scarring of peptic ulceration. A post-bulbar deformity (3 patients) was characterized by a barium pool in a crater-like depression in the cap apex or the post-bulbar region; a scarred cap was found in 8 patients, and 1 patient showed coarsened mucosal folds. Duodenal ulcers were present in 6 of the 111 patients. The first type of duodenal deformity permits categorical diagnosis of cap abnormality due to underlying pancreatitis when other clinical aspects of the patients' history are studied, but the deformity of the cap simulating scarring is more difficult to diagnose; in the absence of duodenal ulceration, it cannot be definitely attributed to pancreatic disease.

- 11558 KIDNEY FUNCTION IN EXPERIMENTAL PANCREATITIS. (Ger.) Diwok, K. (U. Rostock, Germany), J. Dabels and E. Dabels. Zschr. Ges. Inn. Med. 21(10):312-315, 1966.

Kidney function was tested by phenol red excretion in normal rats, rats with HgCl₂ poisoning (2 mg/kg, 16 hr. before testing), or rats with acute hemorrhagic pancreatitis induced by admin. of sodium taurocholate (0.5 ml of 3% soln.) into the temporarily (3 min.) ligated bile duct under ether anesthesia. In normal rats, dye extinction values at 1, 10, 20, and 30 min. were 0.075, 0.03, 0.017, and 0.011,

esp. In rats with $HgCl_2$ poisoning, the extinction value after 1 min. was 0.172, and the other values were also significantly elevated. In rats with acute hemorrhagic pancreatitis of 5-6 hr. duration, phenol red extinction values resembled those after $HgCl_2$ poisoning (0.171 after 1 min., 0.04 after 30 min.); in these 2 groups, the extreme scattering of the 1-min. values suggested both renal tubular damage and general circulatory damage. Av. values in these 2 groups were not significantly different. In rats with pancreatitis of 3-4 days duration, the av. dye extinction values at 1, 10, 20, and 30 min. were slightly above normal (0.086, 0.034, 0.025, and 0.02, resp.), but this difference was not statistically significant.

- 1559 HISTOPATHOLOGY OF EXPERIMENTAL PANCREATITIS IN THE DOG. WITH MODIFICATION RESULTING FROM WHOLE BODY HYPOTHERMIA. (E.) Eichelster, P. (Edward J. Meyer Mem. Hosp., Buffalo, N. Y.), W. G. Schenk, Jr. and E. F. Schueller. *Arch. Surg. (Chicago)* 93(4):606-613, 1966.

Longrel dogs (9-27 kg) used in this study were fasted for 12 hr. prior to aseptic surgery. The duodenum was divided at the pylorus and 4 cm distal to the duct of Santorini. Both ends of the duodenal segment were closed and the pylorus joined to the distal duodenum. The common bile duct was ligated. Thirteen operated animals were used as controls; 22 operated dogs were used in the hypothermic group. An arteriovenous shunt from the carotid artery to the jugular vein through a 2-4-m segment of polyethylene tubing immersed in a water bath cooled, and then maintained the body temperature at 28° for 19 hr. After hypothermia the blind duodenal segment was decompressed by side-to-side duodenojejunostomy, and the ligature on the bile duct removed. Rewarming to 37°C was done by the previous technic using a bath at 42°C. The animals received penicillin and streptomycin during the warming period and for 2-3 days afterward; 1-1 1/2 liters of physiological saline were infused. When animals died or when they were killed at 9-72 hr., specimens were taken from the head, tail and uncinate process of the pancreas, fixed and prepared for histologic examination. The 13 dogs which did not undergo hypothermia all died from 12-31 hr. after construction of the blind duodenal loop. The histopathology of the pancreas was uniformly one of acute hemorrhagic pancreatitis very similar to that seen in man. If whole body hypothermia was instigated within 4 hr. following closure of duodenal loop, pancreatitis was prevented. Hypothermia achieved later than 5 hr. after closure of loop enabled the animals to survive (with decompression of loop) but these animals always showed evidence of focal pancreatitis and scarring. The histopathologic picture corresponds completely to that in man with acute hemorrhagic pancreatitis. There is a reflux of activated pancreatic enzymes into the organ which digest first the vessel walls causing hemorrhage and then the acini from the basal side.

- 1560 EXPERIMENTAL STUDIES ON THE FUNCTION AND HISTOLOGICAL CHANGES OF THE PANCREAS AFTER PANCREATOJEJUNOSTOMY. (Jap.) Tokuka, T. (Kanazawa U. Sch. Med., Japan). *Nippon Geka Hokan (Arch. Jap. Chir.)* 36(6):1530-1540, 1965.

Dogs underwent ligation of the pancreatic duct and removal of part of the tail of the pancreas, which was then anastomosed into the jejunum by an insertion method. Digestion and absorption decreased to an av. of 85.2% postoperatively, but later returned to normal levels (av. 94%). The pancreas underwent necrosis beginning at the site of pancreatojejunostomy. The pancreatic duct was patent through the necrotic tissue after 1 wk., but it remained patent even after 8 wk., when the intrajejunal portion of the pancreas had sloughed off and the surface of the end of the pancreas was covered by intestinal mucosa. The edematous pancreatitis produced in the residual stump by pancreatic duct ligation was improved following pancreatojejunostomy. Appetite and wt. loss was seen after pancreatic duct ligation in all animals, but none of the dogs with pancreatojejunostomy died. These dogs gradually improved, and wt. loss was reduced.

LIVER AND BILIARY TRACI
GENERAL

- 1576 ¹³¹I COLLOIDAL ALBUMIN AS AN AGENT FOR SCANNING LIVER AND SPLEEN. AN EXPERIMENTAL STUDY IN ANIMALS AND MAN. (E.) Loken, M. K. (U. Minnesota Med. Ctr., Minneapolis), E. V. Staab and A. W. Shea. Invest. Radiol. 1(4):259-300, 1966.

Measurements of the clearance of iodine¹³¹ (¹³¹I) colloidal albumin (200 μ c) from the liver and spleen on 20 patients showed that colloidal albumin which is rapidly taken up by cells of the reticuloendothelial system is cleared too rapidly to permit a uniform scan to be obtained. However, when the ¹³¹I colloidal albumin was admin. simultaneously with 4 mg/kg of stable colloidal albumin, essentially uniform and satisfactory scans were obtained with 25 patients. Without the use of the stable colloidal albumin, the radioactivity dropped to less than 50% within the first hr. whereas with the stable albumin, the 50% clearance was not reached until approx. 3 hr., which is comparable to results obtained with ¹³¹I rose bengal. Since the radiation dosage is lower and the clearance more rapid with ¹³¹I colloidal albumin (allowing repeated studies or other radioisotope studies the following day), in some situations scans with colloidal albumin would be preferred to those obtained with ¹³¹I rose bengal or colloidal gold¹⁹⁸. Although the spleen was successively visualized with colloidal albumin, Hg¹⁹⁷ mercurihydroxypropane was preferred since the scans were better and, in addition, information concerning function can be obtained at the same time. All scans were started a few min. after admin. of the colloidal albumin and required from 40-120 min. to perform.

- 1577 EVOLUTION OF SURGICAL TREATMENT OF PROLONGED ICTERUS FROM 1957-1964. (Fr.) Nana, A., C. Mircioiu, E. Neumann and M. Simu. Lyon Chir. 62(3):356-362, 1966.

Comparison of the results obtained from two types of surgical treatment for prolonged jaundice, that is, (I) choledochotomy with an external (Kehr) drainage and (II) the latter plus a neurectomy around the hepatic artery, indicates that the latter technic is the preferable one, although the numbers in each group, 9 and 4, resp., were not large enough for a conclusive statement. In Group I, the results were excellent in 3 cases, satisfactory in 4 cases and 2 died. Within this group, 3 patients underwent excision of the hilar ganglion and 1 underwent gallbladder removal, in addition to the described procedure. In Group II, the results were excellent in 5 cases, satisfactory in 6 cases and 2 died. Two of these patients underwent gallbladder removal in addition to the described procedure. In 3 of the total 4 deaths advanced liver cirrhosis was evident. In total, the av. duration of jaundice was 4 mo.; the results were poorer when surgical intervention was not performed within 6 wk.-2 mo. of the development of the jaundice. Age of patients ranged between 20-70 yr., with 8 cases in the 20-30-yr. range and 5 in the 50-60-yr. range. The assumed improvement caused by the hepatic arterial neurectomy is due to the fact that it improved the lymph and blood flow in the liver.

- 1578 IS PORTO-CAVAL ANASTOMOSIS THE BETTER TREATMENT OF PORTAL HYPERTENSION OF INTRA-HEPATIC ORIGIN? (It.) Zannini, G. (U. Naples, Italy) and F. Mazzeo. Fegato 12(1):35-44, 1966.

Cases of portal hypertension (61) of intrahepatic origin observed between 1963 and 1965 are described. Thirty-eight occurred in men and 23 in women between the ages of 10 and 64 and lasting for a period of 2 mo. to 5 yr. Serious complications such as confirmed jaundice, hyperammonemia, and extensive ascites eliminated 17 from surgical procedures. Taking into consideration the degree of portal hypertension, presence of enterorrhagia or ascites, age and the degree and nature of the disease, the authors performed 24 porto-systemic anastomoses, 18 splenectomies, and 2 pneumophrenohepatopexias with Ivalon. Side-to-side porto-systemic anastomosis was the most successful in treating portal hypertension caused by intrahepatic block and was used on all cases but 1. All splenectomies but 1 were successful. Of the 12 patients still living 7 showed optimal results with a progressive return to normal, 3 showed good progress, but intensive medical care with

LIVER AND BILIARY TRACT

albumin, plasma and hormone treatment had to be admin. to reach a stable equilibrium. Two cases were mediocre because of persistent ascites, recurrent hemorrhage and in 1 case serious encephalopathy. Among causes of death were cardiac infarct, irreversible fibrinolytic crisis and hepatic coma.

- 11579 ULTRAMICROSCOPIC HEPATIC CHANGES IN PATIENTS WITH DUBIN-JOHNSON SYNDROME. (It.) Barone, P. (U. Messina, Italy), C. Inferrera and F. Tigano. Fegato 12(1):53-68, 1966.

In 2 brothers suffering from chronic idiopathic jaundice with modification of hepatic parenchymal pigmentation, liver biopsies were made 48 hr. and 3 mo. after inj. of sulfobromophthalein and specimens were examined by electron microscopy. Serum levels of bilirubin were not changed significantly after inj. or at the times of biopsy. Intense vacuolization and enlargement of the hepatic cells were accompanied by increased pigmentation in the centrolobular cells, leading to a characterization of the cases as intermediate forms between Dubin-Johnson's and Rotor's syndrome. Electron micrographs showed reduction and fragmentation of the rough endoplasmic reticulum, while the smooth endoplasmic reticulum and Golgi membranes appeared swollen. An intracellular accumulation of bile was found in approx. 10% of the cells observed. Pigment accumulation was greatest in the periphery ranging from areas of dense vesicular accumulation to large clumpings with clear centers and dense outer shells. Irregular forms were prevalent in the reduced mitochondrial apparatus. Cytoplasmic vacuolization of Kupffer cells was common, particularly immediately after the sulfobromophthalein inj. It is concluded that these intracellular, cholestatic changes represented morphological sequelae of impeded excretion of hepatic bile.

- 11580 PROGNOSIS AND THERAPY OF HEPATIC COMA. (It.) Agostoni, A. (U. Milan, Italy) and G. C. Secchi. Gazz. Sanit. 37(1-2):28-36, 1966.

A review of diagnosis and differential diagnosis of hepatic comas includes sections on etiology, precipitating factors, and both specific and supportive therapy. Comas occurring in the presence of acute hepatic disease are said to result in 60% mortalities, as compared to a rate of 66% for those occurring in the presence of chronic hepatic disorders.

- 11581 ULTRAMICROSCOPIC HEPATIC LESIONS IN SUBACUTE AND CIRRHOTIC ALCOHOLIC HEPATITIS. (Fr.) Albot, G. (Hotel-Dieu, Paris) and M. Parturier-Albot. Sem. Hop. Paris 42(29):1757-1771, 1966.

Light and electron microscopic studies were made of liver biopsy specimens from 2 patients with subacute hepatitis in the presence of so-called clear cells. In both patients, cellular changes included the presence of deformed mitochondria with short, rarefied crests and opaque, granular matrices; a heavily vacuolar, agranular, endoplasmic reticulum and ergastoplasm, the latter frequently showing dispersed ribosomes; hypertrophy of the Golgi apparatus; and widening of the intercellular spaces, due to a substance excreted by the unaltered bile ducts. In the patient with subacute, alcoholic, fatty hepatitis, these changes were supplemented by a considerable accumulation of lipids within the hyaloplasm, resulting in vacuoles whose membranes originated in the endoplasmic agranular reticulum. In the patient who showed transition from hepatitis into cirrhosis, they were supplemented by characteristic lesions of the sinusoidal capillaries and Disse's fissure, including the type of hypertrophy of the microvillae and increased density of the hepatocytic blood pole which frequently accompanies lesions of the bile ducts. All of the lesions reported were ascribed specifically to the effects of alcohol.

- 11582 THE ACTION OF A TOTAL LIVER EXTRACT ON THE COURSE OF CHOLESTATIC LIVER LESIONS AND ON THE REGENERATIVE CAPACITY OF LIVER PARENCHYMA. (Ger.) Loddi, L. (U. Florence, Italy) and F. Grifoni. Aerztl. Forsch. 20(6): 314-316, 1966.

In rabbits with ligated common bile ducts, treatment with the fresh liver extract Ripason (equivalent of 0.3 g/kg/day i.m., beginning on the day of surgery or 10 days previously) had no effect on the mechanical phenomena resulting from cholestasis (dilation of intra- and extrahepatic bile ducts or venous obstruction in the

LIVER AND BILIARY TRACT

ver), but both progressive and regressive phenomena were decreased, and protection of the cytoplasmic RNA was seen. In hepatectomized rabbits treated with a larger dose of Ripason (0.5 g/kg/day, regimen as before), liver regeneration was more rapid and degenerative changes (including connective tissue proliferation) were less marked than in controls. The fluctuation in hepatic lipids was also less marked than in controls. Polysaccharide levels paralleled glycogen levels, which decreased more markedly in treated animals (especially in the first 5 days, then normalization after about 2 wk.) due to the increased requirements of the regenerating tissue. Cytoplasmic RNA was higher in treated animals, but DNA production was increased only slightly in the initial stages of regeneration. Liver alkaline phosphatase activity was higher and succinic dehydrogenase activity somewhat reduced in treated animals in the first 5 days; normalization of the decreased serum proteins was more rapid, and the fluctuation in serum alkaline phosphatase was less marked.

583 EVALUATION OF OPERATIVE WEDGE BIOPSY OF THE LIVER. (Rus.) Kalashnikov, S. A. Vestn. Khir. Grekov. 96(5):28-31, 1966.

Liver changes due to surgery and anesthesia were studied in 390 specimens from patients operated for gallbladder and biliary tract diseases (259), liver cirrhosis and portal hypertension (63), and stomach cancer and other abdominal diseases (24). Stasis was seen in 10 specimens taken at the end of surgery, but it had been absent at the beginning of surgery in 7 cases. Accumulation of WBC in the capillaries was seen in 5 specimens, hemorrhages in the parenchyma and portal areas and marked polyemia in 11 cases, and no changes in 74 specimens taken at the beginning of surgery. These changes were noted in 40, 21, and 42, resp., of 103 biopsies taken at the end of surgery. Decreased liver glycogen was a result of ether toxicity and its extent depended upon the duration of ether narcosis. Liver glycogen was almost unchanged after nitrous oxide narcosis. Pathological changes in the gallbladder walls were reflected by morphological changes in the adjacent liver tissue. The most reliable information on the nature of morphological changes in the liver resulting from the underlying disease was obtained from biopsies taken from the anterior portion of the left lobe at the beginning of surgery under nitrous oxide narcosis.

584 THE INFLUENCE OF RESECTION OF THE STOMACH WITH SUBSEQUENT ENTEROPLASTY ON SOME FUNCTIONS OF THE LIVER. (Rus.) Vikulova, N. N. (Pavlov Med. Inst., Leningrad). Khirurgia (Moskva) 42(5):23-26, 1966.

Dogs with Pavlov fistulas, the 15-25% loss of wt. during the first mo. after surgery was restored within the next 2-3 mo. The latent period of bile yield, bilirubin and bile acid content of the bile, serum bilirubin, fasting blood sugar levels, and plasma fibrinogen remained unchanged following gastric resection with total intestinal enteroplasty. During the early postoperative period, the volume and duration of bile excretion were markedly reduced and the biliary solid residue content was increased; bile excretion was normalized 5-6 mo. after surgery. After p.o. and i.v. loading with galactose, the blood sugar curve was only slightly disturbed; the sugar and postglycemic coefficient showed slight transient increase. The total serum protein content was decreased with an increase in the globulins (especially β and γ -globulins) and a decrease in serum albumins. Normalization occurred after 3-4 mo. The prothrombin time showed a slight transient decrease at first, but returned to its initial level 2-3 mo. after surgery.

585 THE BEHAVIOR OF SERUM LIPIDS IN CHRONIC ALCOHOLISM. (Ger.) Vetter, D. (U. Zurich, Switzerland). Praxis (28):783-790, 1966.

In 150 normal adults, mean serum β -lipoprotein, triglyceride, and cholesterol levels were 320, 127, and 246 mg%, resp. In subjects of normal wt. these values were 300, 99, and 220 mg%, resp. In 101 chronic alcoholics, these values were 300, 125, and 236 mg%, resp., with wide individual variations. Of the alcoholic patients, 70 had proven liver damage (fatty liver in 20, cirrhosis in 29, other liver damage in 21). In the alcoholic patients with normal, fatty, and cirrhotic livers, mean serum values were: β -lipoproteins 300, 420, and 263 mg%, resp.; triglycerides 100, 236, and 81 mg%, resp.; and cholesterol 220, 266, and 199 mg%,

LIVER AND BILIARY TRACT

resp. Mean serum cholinesterase values were 2500, 3597, and 1961 I.U., resp.; the mean value in the entire group of alcoholic patients was 3020. It is concluded that the lipid and cholinesterase levels are elevated in alcoholics with fatty livers, but fall to very low levels in cirrhosis; therefore, determination of serum lipids (especially triglycerides) and cholinesterase will almost always differentiate between fatty liver, which is reversible, and cirrhosis, which is not.

- 11586 SERUM ISOCITRATE DEHYDROGENASE IN OBSTRUCTIVE JAUNDICE. (E.) Watts, C. (Western Infirmary, Glasgow, Scotland). Clin. Chim. Acta 14(2):177-184, 1966.

Enzyme levels were studied in 53 patients with obstructive jaundice due to metastatic malignant tumors (11), malignant disease not involving the liver (14), non-malignant and non-inflammatory cholelithiasis and chronic cholecystitis (20), and acute inflammatory obstruction with fever and/or leukocytosis of non-malignant origin (2). The normal range of serum isocitrate dehydrogenase (determined colorimetrically) in 40 normal subjects was 3-10 U/ml. In the patients with obstructive jaundice, there were 9 cases (17%) with normal values, 15 with minimal elevation (up to 150% of the upper limits of normal), 19 with moderate elevation of the enzyme (from 16-30 U/ml), and 10 (19%) with levels of up to 50 U/ml. Elevated isocitrate dehydrogenase levels were usually associated with factors complicating obstructive jaundice, such as liver metastases and acute inflammation. When inflammation subsided in patients with non-malignant disease, enzyme levels fell to normal.

- 11587 RECOGNITION OF HEPATIC METASTASES THROUGH RADIOISOTOPE COLOR SCANNING. (E.) Baum, S. (Long Island Jewish Hosp., New York), L. Silver and D. Vouchides. J.A.M.A. 197(9):675-679, 1966.

Without previous preparation, 116 patients with suspected liver metastases received Au^{198} (150 μ c i.v.). Liver scans were done 2-48 hr. later using either of 2 scanners with color attachments, using either a 3- or 5-inch NaI crystal; the former had a 19-hole collimeter and the latter, a coarse-focusing 85-hole collimeter. The probes were placed 1 cm and 3 cm, resp., from the body surface. The area of max. count rate was located and the color calibration adjusted so that this activity area appeared red on the scan. Other factors such as speed, spacing, dot count, and (for the photoscanner) density and range differential, were also varied according to the max. count rate, which was usually about 30 min. for each patient. 6000-10,000 cpm. The scanning time was usually about 30 min. for each patient. After radioisotope scanning each patient underwent pathological examination of the liver; the diagnosis was obtained by biopsy in 23 patients, at operation in 61, at necropsy in 23, by operation and autopsy in 8, and by biopsy and operation in 1 patient. In 46 patients the scans were interpreted as showing evidence of space-occupying lesions; liver metastases were later demonstrated in 41 of these patients. No liver lesions of this type were found in the other 5 patients; the accuracy of the scanning technic was 89%. Liver scans were negative for space-occupying lesions in 70 patients; there was only 1 false negative (98% accuracy). In general, the higher the count rate the longer the wavelength of color developed in the scan; thus, red indicated 80-90% radioactivity and green corresponded to 50-60% radioactivity.

- 11588 HEPATIC PROLIFERATIVE RESPONSE TO INSULIN IN SEVERE ALLOXAN DIABETES. (E.) Younger, L. R. (U. Chicago, Illinois), J. King and D. F. Steiner. Cancer Res. 26(7)(Pt. 1):1408-1414, 1966.

In rats with severe diabetes induced 1 mo. previously with a single inj. of alloxan (40 mg/kg i.v.), treatment with insulin (10 U in the first s.c. inj., then 4 U/day) led to marked proliferation of the liver cells. DNA polymerase activity and thymidine uptake by DNA *in vivo* were increased within 24 hr. after insulin was begun, reaching peak levels between 48-72 hr. Total liver DNA increased about 70% in the first 36-72 hr. of treatment. This increase in DNA was accompanied by liver cell proliferation to the same degree as that seen following partial hepatectomy. Hypophysectomy reduced but did not abolish the cellular proliferative response to insulin.

LIVER AND BILIARY TRACT

- 89 CLINICAL AND EPIDEMIOLOGICAL STUDIES ON HEPATOCEREBRAL DISEASE IN JAPAN. (E.) Yoshikawa, M. (U. Tokyo, Japan), T. Mozai and S. Hirai. Progr. Brain Res. 218:269-284, 1966.

This review summarizes studies of hepatolenticular degeneration and hepatic encephalopathy in Japan. In the period 1949-1959, 62 cases of hepatolenticular degeneration were reported. The age range was from 5.5 to 55 yr.; 32 (51.6%) were between 11 and 20 yr. old, and 58 (93.5%) fell in the age range 5-30 yr.; 41 were males, giving a male:female ratio of 2:1. Familial occurrence and consanguineous marriages (mostly between cousins) occurred in 15 families (35%) among the 43 families investigated. Initial symptoms were neurological in 71%, abdominal in 23%, and mental or personality changes in 6%. The most frequent signs and symptoms were the Kayser-Fleischer corneal ring, tremor, and rigidity. Copper metabolism in these patients very closely resembled the fetal copper metabolism; increased copper concentration was found in the liver and brain, and copper depositions occurred in the liver in the form of granules. Occasionally copper granules have been observed in the brain. Wilson's disease and pseudoscleroses (which had been considered separate diseases) were included in the category of hepatolenticular degeneration, although there were some biochemical differences such as the response to chelating agents. The second chapter, on hepatic encephalopathy, discusses the acute form (due to hepatic failure) and the chronic form (due to portal systemic shunt, shistosomiasis japonica and so-called pseudo-ulegria). Ammonia (a stimulant to the limbic system) is regarded as the most important factor in the episodic attack of neuropsychiatric disturbance characteristic of the portal systemic encephalopathy, whereas coma seemed to result from a number of other cerebral depressants (such as short chain fatty acids) in the circulation due to hepatic failure.

- 90 A NEW AND UNPUBLISHED CONTRIBUTION CONCERNING BANTI'S DISEASE. (Fr.) Haeffner, A. (Avicenna Hosp., Rabat, Morocco). Rev. Medicochir. Mal. Foie 41(3):127-142, 1966.

A method for direct measurement of portal vein blood pressure is described. In 15 normal subjects, the av. difference between blocked ileal pressure (measured in cm water) and av. portal pressure was 13 cm. In 15 patients with Banti's disease (North African splenomegaly) the av. difference was 26.2 cm. In the 5 patients with early disease (without cirrhosis) this av. difference was 31.5 cm; in the 10 patients with advanced disease, it was 23.6. In contrast to the almost 100% increase in differential pressure in Banti's disease, there was a decrease in alcoholic cirrhosis. In Banti's disease, liver blood flow was increased about 40% (the portal vein circulation rate was 12-20 cm/second); in alcoholic cirrhosis the blood flow was decreased (to under 10 cm/second).

- 91 LIVER FUNCTION STUDIED BY LIVER PERFUSION. (E.) Mayes, P. A. (Royal Vet. Coll., London, N. W. 1) and J. M. Felts. Excerpta Med. (Int. Congr. Ser.) (115):16-29, 1966.

A system for the perfusion of rat livers with oxygenated, defibrinated blood at 38°C, with provision for the addition of reactants and removal of samples for analysis, was devised to study liver function with particular respect to the metabolism of free fatty acids and the control of ketogenesis, the role of the liver in the emulsification of dietary fat (specifically the chylomicrons), and the direct effect of hepatotoxins on liver function. Defibrinated blood was employed for perfusion to obviate the use of heparin, which causes release of lipoprotein lipase into the circulation where the enzyme hydrolyzes the triglycerides of lipoproteins and chylomicrons to free fatty acids. Antiketogenesis in the perfused liver could be completely accounted for by the enhanced ability of the liver to esterify fatty acids, diverting them from the pathway of oxidation. In the absence of heparin, chylomicron triglycerides were not taken up or oxidized to any significant extent by the isolated rat liver. In the perfused rat liver, CCl₄ caused an immediate reduction in the rate of secretion of very low density lipoproteins, whereas the rate of secretion of these lipoproteins was maintained at the control rate for at least 2 hr. after admin. of ethionine. Whereas CCl₄ had no immediate effects upon the rate of oxidation of C¹⁴-oleate to C¹⁴O₂, serum free fatty acids, or the blood

LIVER AND BILIARY TRACT

glucose level, ethionine produced some acceleration in the rate of $C^{14}O_2$ production and the formation of C^{14} -ketone bodies.

- 11592 THE KARYOGRAM OF THE HUMAN LIVER UNDER NORMAL AND PATHOLOGICAL CONDITIONS (Ger.) Altmann, H. W. (Pathol. Inst., U. Wurzburg, Germany), K. Loeschke and K. Schenck. *Virchow. Arch. Path. Anat.* 341(2):85-101, 1966.

Chromosome counts were made in 49 normal liver specimens (from stillborn and newborn to aged subjects) and 11 patients with hepatitis (4), post-hepatitis syndrome (4), or cirrhosis (3). The percentages of tetraploid and polyploid cells tended to increase with age in the normal subjects. These data were presented graphically (incidence of various karyotypes against log nuclear surface area); the highest of the 2-3 peaks represented the diploid population. The diploid peak was shifted to the right in the karyograms from patients with epidemic hepatitis and the post-hepatitis syndrome. Polyploid and tetraploid cells were especially frequent in the latter group. In the cirrhosis patients, the frequency peak of the smaller nuclear surfaces was essentially identical to that seen in younger normal subjects; the large surface peaks were above normal in 2 cases (in 1 of them the tetraploid peak was larger than the diploid peak) and below normal in the third. The diagnostic value of these findings is discussed.

- 11593 BSP RETENTION DURING TOTAL FASTING. (E.) Verdy, M. (Hotel Dieu, Montreal, Canada). *Metabolism* 15(9):769-772, 1966.

In 26 obese women fasted for 1 wk., the 45-min. sulfobromophthalein (BSP) value increased from $5.05 \pm 0.8\%$ to $14.5 \pm 2.2\%$ after 3 days, and to $16.9 \pm 2.6\%$ after 7 days. Cystine (10 g/day p.o. for 2 days) was admin. to 3 cases; it did not correct abnormal BSP retention, but rather was associated with increased retention in all cases. Serum transaminases increased during the first several days in 25% of the group, but returned to normal on day 7. Lactic dehydrogenase values were not significantly changed. It is concluded that abnormal retention of BSP does not indicate liver cell damage, but rather a metabolic defect responsible for abnormal excretion of the dye.

- 11594 VOLUMETRIC, HEMODYNAMIC AND EXCRETORY CHARACTERISTICS OF THE LIVER IN ACROMEGALY. (E.) Preisig, R. (Columbia U. Coll. Phys., New York, N. Y.), T. Q. Morris, J. C. Shaver and N. P. Christy. *J. Clin. Invest.* 45(9):1379-1387, 1966.

The hepatic parenchymal and biliary functions of 6 men and 5 women with clinical features of acromegaly (age 41-66 yr.) were analyzed by determination of storage capacity and transfer max. for sulfobromophthalein (BSP). BSP transfer max. was increased in every patient, with an av. of 17.6 mg/min. (normal 9.6 ± 1.9) in the 6 men and 13.5 mg/min (normal 7.2 ± 1.9) in the 5 women; BSP storage capacity was within normal limits. Liver vol. (calculated from measurements of hepatic photoscans) was augmented by about 50% in 5 of 7 patients; splanchnic blood flow and vol. were normal. This, in addition to increased hepatic extraction for indocyanine green and oxygen, suggested a relative decrease in tissue perfusion that was proportional to the increment in the hepatic mass. It is suggested that changes in enzymatic processes within parenchymal cells are responsible for augmented excretory capacity for BSP.

- 11595 PIGMENTARY LIVER DISEASE IN HOWLER MONKEYS. (E.) Maruffo, C. A. (Oregon Reg. Primate Res. Ctr., Beaverton), M. R. Malinow, J. R. Depaoli and S. Katz. *Am. J. Path.* 49(3):445-456, 1966.

The livers of 290 free-ranging howler monkeys (*Alouatta caraya*) captured in northern Argentina were examined. Variable amounts of lipofuscin were found in the parenchymal cells; the granules, which were found in animals of all ages and both sexes, were argyrophilic, periodic acid-Schiff-positive after diastase digestion, sudanophilic, and autofluorescent. The amount of pigment increased with age in animals of both sexes, especially after puberty, but no sex-related differences were noted. In those monkeys with heavier hepatic pigmentation, focal necrosis, diffuse fatty metamorphosis, multinucleated hepatocytes, and nodules of regeneration measuring 1-3 mm were seen. Examination by electron microscopy of 2 animals showed the

LIVER AND BILIARY TRACT

of fuscin granules to be osmiophilic and composed of aggregates of dense particles and a globular substance of lesser density; this pigment was also found in Kupffer cells. Blood biochemical values determined in 5 monkeys were normal as compared with human standards. The similarities of this disorder to chronic familial jaundice and Dubin-Johnson syndrome were noted.

- 96 LIVER FUNCTION IN APPARENTLY HEALTHY CHRONIC ALCOHOLIC PATIENTS. (E.) Knott, D. H. (U. Tennessee, Knoxville) and J. D. Beard. Am. J. Med. Sci. 252(3):260-264, 1966.

Chronic liver dysfunction was diagnosed in 30 chronic alcoholic, well-nourished patients (18 male, 12 female, age 21-56 yr.) by measuring sulfobromophthalein retention, serum glutamic-oxalacetic transaminase, serum isocitrate dehydrogenase, serum glutamic-pyruvic transaminase, and total bilirubin, in decreasing order of frequency of abnormal findings. The total serum proteins and albumin/globulin ratio were normal in all cases. Only 7 patients had symptoms of liver disease. After 3 wk. of hospitalization and treatment consisting of abstinence from alcohol, a regular diet and administration of a phenothiazine psychotropic drug (TPS-23 or Serenitil), all normal liver tests showed significant normalization. The frequency of residual abnormalities in the liver function tests was sulfobromophthalein retention, serum isocitrate dehydrogenase, serum glutamic-pyruvic and glutamic-oxalacetic transaminases, and bilirubin, in decreasing order. Liver biopsy from 1 patient showed minimal necrosis and a moderate but generalized infiltration of fat, primarily located in the centrilobular area.

- 97 CERULOPLASMIN SERUM LEVEL IN LIVER DISEASES. (E.) Hauftova, D. (Palacký U., Olomouc, Czech.) and J. Slaviček. Rev. Czech. Med. 12(3):147-154, 1966.

Serum ceruloplasmin levels were determined in 114 healthy blood donors (62 male, 52 female), 57 patients with liver cirrhosis of various origins, 25 patients with infectious hepatitis, and 35 patients with obstructive jaundice. Normal values were 0.45 ± 0.08 , regardless of age or sex. In Laennec's and postnecrotic cirrhosis, ceruloplasmin values were elevated in 33%, normal in 33%, and reduced in 33% of the group. Low ceruloplasmin levels corresponded to low albumin levels and elevated bilirubin levels. In infectious hepatitis of a normal or mild nature, ceruloplasmin throughout the icteric period was elevated, being highest at onset of jaundice (0.68 ± 0.10); it gradually declined, but at the end of the icteric period it still was significantly higher than normal (0.57 ± 0.13). Serum ceruloplasmin was elevated in obstructive jaundice (0.67 ± 0.20), but there was no difference in ceruloplasmin levels according to the etiology of the obstructive jaundice (malignant, benign and biliary cirrhosis). Ceruloplasmin estimations did not have differential diagnostic value in discriminating between infectious and obstructive jaundice.

- 98 THE EFFECT OF ETHYL α -p. CHLOROPHENOXYISOBUTYRATE ON ETHANOL-INDUCED HEPATIC STEATOSIS IN THE RAT. (E.) Brown, D. F. (Albany Med. Coll., Albany, N. Y.). Metabolism 15(10):868-873, 1966.

Rats were divided into 4 groups of 6 and treated with the following regimens: Groups 1 and 2 were fed a normal diet, Groups 3 and 4 received the same diet and ethyl α -p-chlorophenoxyisobutyrate (CPIB; 0.25% by wt.); in 2 wk. all food was withdrawn, and Groups 1 and 3 were treated with ethanol (6 g/kg), while Groups 2 and 4, an isocaloric amount of glucose. In rats pretreated with CPIB and given ethanol, serum free fatty acid (FFA) and liver triglyceride levels decreased, while liver phospholipid levels increased. Liver triglycerides were higher and liver phospholipids lower in CPIB-treated rats given alcohol than in CPIB-treated rats fed glucose. There was no difference in adipose tissue lipoprotein lipase content between CPIB-treated and untreated animals 16 hr. after glucose ingestion. Modification by CPIB of lipid changes induced by alcohol suggests that CPIB may interfere with adipose tissue lipolysis, but the effect of alcohol may also be modified after direct effect of CPIB on hepatocellular function.

LIVER AND BILIARY TRACT

- 11599 DISTRIBUTION OF LIPIDS IN SUBCELLULAR FRACTIONS OF FATTY LIVERS. I. LIPIDS IN LIVER CELL FRACTIONS OF RATS FED A HIGH FAT AND CHOLESTEROL DIET. (E.) Takasugi, Y. (Hokkaido U. Sch. Med., Sapporo, Japan) and Y. Imai. J. Biochem. (Tokyo) 60(2):191-196, 1966.

Rats were fed diets containing cholesterol and coconut oil or linoleic acid, and the conc. of lipids was determined in serum and ultracentrifugal fractions of the liver. A high-fat diet alone produced some minor fatty infiltration of the liver, but rats fed both cholesterol and a high-fat diet showed accentuated lipid deposition. The chief site of exogenous lipid deposition in the liver was associated first with a centripetally migrating fraction. Serum cholesterol was elevated only in those rats fed cholesterol and linoleate. A slight increase in cell particulate phospholipid levels occurred in livers of the linoleate-fed rats.

- 11600 THE INFLUENCE OF IRRITATION OF THE CENTRAL NERVOUS SYSTEM ON THE EVOLUTION OF HEPATIC LESIONS PRODUCED BY EXPERIMENTAL TRANSITORY BILIARY STASIS. (Rum.) Leporda, G. (Dept. Biol., Rumanian Acad. Sci., Iasi), S. Dolinescu, G. Scripcaru and L. Wasserman. Rev. Medicochir. Iasi 70(2): 445-450, 1966.

The effects of temporary biliary stasis (ligation of the choledocus for 12-14 or 11-160 days) on the liver of dogs were essentially identical with those of previous studies, except that some parenchymal changes become irreversible even after only 1-2 wk. of biliary stasis, indicating the beginning of a cirrhotic process. Irritation of the central nervous system (CNS) by inj. of 2% KCl soln. into the spinal canal (8-12 suboccipital punctures were performed) in 4 normal dogs resulted in such an intense liver congestion that the picture could be easily taken as representing cardiac liver stasis. After 14-40 days of biliary stasis, this treatment caused an intensification of the sclerosing process, a congestion involving the entire liver lobe, lipid dystrophy, granulo-vacuolar dystrophy of the parotid gland of an unprecedented intensity, and a number of biliary thrombi. In 4 other dogs receiving benzedrine as a CNS irritant (4.0 mg/day p.o. for 52 days), the liver changes were no different from those in control dogs during and after biliary stasis. The areas of sclerosis resulting from experimental biliary stasis remained unchanged after either KCl or benzedrine admin. However, CNS irritation with KCl, with an especially damaging effect on hepatocytes, tended to aggravate pre-existing hepatic lesions.

- 11601 ANTIBODY TO LIVER IN LUPOID HEPATITIS. (E.) Johnson, G. D. (Canadian Red Cross Mem. Hosp., Berkshire, England), E. J. Holborow and L. E. Glynn. Lancet 2(7460):416-418, 1966.

Serum was taken from 21 patients with probable or possible lupoid hepatitis (10 and 6 cases, resp.), or liver disease other than lupoid hepatitis (5 cases), and from 45 healthy subjects (the controls) and tested by indirect immunofluorescence method of Coons and Kaplan (1950). Of the 21 sera from liver disease patients, 5 gave positive staining for bile canaliculi, 8 were positive for glomeruli, and 11 were positive for smooth muscle (stomach). None of the 45 control sera gave bile canalicular staining. Because smooth muscle staining was found in the absence of glomerular and/or canalicular staining (7 sera), and glomerular staining occurred without canalicular staining (1 serum), it is suggested that the staining is due to tissue-specific antibodies rather than common elements in the tissues studied. This pattern of staining involving bile canaliculi appears to be the first demonstration in liver disease of an antibody reacting with a component of the liver parenchyma itself.

- 11602 ONSET OF MANIFESTATIONS OF HEPATIC PORPHYRIA IN RELATION TO THE INFLUENCE OF FEMALE SEX HORMONES. (E.) Zimmerman, T. S. (U. Minnesota Hosp., Minneapolis), J. M. McMillin and C. J. Watson. Arch. Intern. Med. (Chicago) 118(3):229-240, 1966.

A group of 54 women with hepatic porphyria of all types was studied; 11 women (20%) had exacerbations associated with pregnancy, the menstrual cycle or both. Determinations were made of urinary porphobilinogen, urinary and fecal porphyrins,

LIVER AND BILIARY TRACT

of urobilinogen retention, alkaline phosphatase, and serum bilirubin. Serial observations of urinary porphyrin and precursor excretion over relatively long periods failed to reveal significant changes in relation to clinical manifestations of the phase of menstrual cycle or the effect of oophorectomy. Administration of estrogens was associated with the first appearance or an exacerbation of hepatic porphyria in patients; 10 of these had cutaneous manifestations; 1 had only acute neuropsychiatric symptoms and 1 had both. Skin lesions disappeared in 5 patients in whom estrogens were discontinued. A majority of patients with some endocrine involvement had the symptoms of porphyria showed some evidence of abnormal liver function.

03 PROGNOSTIC VALUE OF SERUM γ -GLUTAMYL TRANSPEPTIDASE ACTIVITY IN LIVER DISEASE. (E.) Villa, L. (U. Milan, Italy), N. Dioguardi, A. Agostoni, G. Ideo and R. Stabilini. *Enzym. Biol. Clin.* (Basel) 7(1-2):109-114, 1966.

Serum γ -glutamyl transpeptidase (γ -GT; expressed as μ moles β -naphthylamine liberated/100 ml serum), glutamic-pyruvic transaminase (SGPT), alkaline phosphatase (AP), leucine aminopeptidase (LAP), and bilirubin levels were determined in normal subjects and patients with liver disease. Mean serum γ -GT activity was 19.5 U in 53 normal subjects, 156 U in viral hepatitis (25 cases), 163.5 U in obstructive jaundice (14 cases), 183.7 U in intrahepatic cholestasis (7 cases), 103 U in cirrhosis with hypertrophic liver (23 cases), 32.2 U in cirrhosis with liver atrophy (30 cases), and 79.4 U in cardiac cirrhosis (6 cases). Although serum γ -GT activity was increased in acute viral hepatitis, there was no consistent pattern of enzyme activity during the course of the disease. A patient with chronic hepatitis and jaundice of several months duration showed, on admission, elevated serum levels of LAP and γ -GT. Serum bilirubin levels increased and γ -GT levels decreased during the 2 weeks prior to death; the liver also decreased in size. Lowered values of γ -GT activity were observed 2 weeks prior to death in 3 other patients with chronic hepatitis. One patient with choledocholithiasis and obstructive jaundice of 2 months duration had elevated serum bilirubin, γ -GT, AP, LAP, and SGOT on admission. During the period of observation, the jaundice was resolved and serum AP and LAP diminished, but the serum γ -GT levels rose progressively. Following surgical removal of biliary calculi, serum γ -GT activity remained elevated for 20 days, when all other tests had returned normal.

04 THE ESSENTIAL ROLE OF THE LIVER IN DETOXIFICATION OF ENDOTOXIN. (E.) Farrar, W. E., Jr. (Walter Reed Army Inst. Res., Washington, D. C.) and L. M. Corwin. *Ann. N. Y. Acad. Sci.* 133(2):668-684, 1966.

Endotoxin detoxifying activity of guinea pig was determined in saline supernatant centrifuged solution by incubating with a known amount of endotoxin. Diluted reaction mixture was then assayed by injection into 11-day-old chick embryos. Lethality of endotoxin for chick embryos had been shown to be proportional to dosage. A high degree of activity was also found in liver (88%). Damage to the liver parenchyma by CCl_4 increased susceptibility of the animals 200-fold. Max. susceptibility was correlated with a max. amount of necrosis in the liver, and liver tissue removed at this stage of intoxication showed almost no ability to detoxify endotoxin *in vitro*. Healing of the liver lesion was associated with a return toward normal resistance to endotoxin by the animal and with a reappearance of endotoxin-inactivating capacity of liver tissue homogenates. Inactivation of endotoxin by liver homogenates and mitochondria appeared to be due to activation and oxidation of the fatty acid portion of the endotoxin molecule, implying that the lipid portion of endotoxin is necessary for its toxicity. When the effects of CCl_4 , allyl alcohol, and ethionine were compared, a close correlation was found between the effect of the hepatotoxin and nicotinamide-adenine-dinucleotide linked substrate oxidation by liver mitochondria (washed or acetone dried) and its effect on the susceptibility of the guinea pig to endotoxin. Allyl alcohol and ethionine, which had much less effect than CCl_4 on both fatty acid oxidation by liver mitochondria and on the susceptibility of the guinea pig to endotoxin could not be demonstrated to reduce the endotoxin-inactivating capacity of guinea pig tissues.

05 FORMATION OF GLUCURONIDE AFTER ORAL LOADING WITH ACETANILIDE IN PATIENTS WITH CHRONIC HEPATITIS AND CIRRHOSIS OF THE LIVER. (Ger.) Hammar, C.-H.

LIVER AND BILIARY TRACT

(Johannes Gutenberg U., Mainz, Germany) and W. Prellwitz. Klin. Wschr. 44(17):1010-1014, 1966.

Twelve patients with hepatitis, 12 patients with cirrhosis of the liver (proved by laparoscopy and histology), and 12 patients free of liver disease (controls) were studied; 6 patients from each group received acetanilide (800 mg) and the other 6 patients received a higher dose of acetanilide (1200 mg). Blood samples were taken at 2, 6, and 24 hr.; the 24-hr. urine was also analyzed. With the lower dosage of acetanilide, there was no significant difference between the experimental and control subjects. At the higher doses of acetanilide, patients with liver disease showed a decrease in the glucuronide, and an increase in free N-acetyl-p-aminophenol; no free acetanilide could be detected. A decrease in glucuronyltransferase activity leading to decreased N-acetyl-p-aminophenol glucuronide formation is postulated.

11606 METHODS FOR EXTRACORPOREAL HEPATIC ASSIST. (E.) Eiseman, B. (U. Kentucky Coll. Med., Lexington), J. Van Wyk and W. O. Griffin, Jr. Surg. Gynec. Obstet. 123(3):522-530, 1966.

Patients with reversible hepatic failure can be improved by extracorporeal pig liver perfusion. The liver, washed free of its own blood, is perfused from arterio-venous shunts in both forearms separately through the hepatic artery and portal vein in the pig liver. A single venous line returns the effluent through a bubble trap and pump to the patient. The extracorporeal liver is extremely sensitive to decreased temperature and pH and at first takes up to 250-500 ml of blood. Liver temperature is maintained at 38°C by a heat exchanger; acidosis is avoided by perfusion admin. of NaHCO₃ to the patient; hypotension in the patient is prevented by appropriate transfusion. Four-hr. perfusions at 3-5-day intervals as clinically indicated yield the best results. A battery of neurologic, physical, liver and blood tests are done prior to, during and after the perfusion. Detailed directions are given for preoperative donor preparation, excision, exsanguination, care and handling of the liver, instrumentation required, anticoagulant measures, and preparation of the patient. Experience during 27 perfusions on 16 patients provides the basis for the technic described.

11607 THE HEPATIC LYMPHATIC SYSTEM IN THE PRESENCE OF PHYSICAL PATHOLOGY CONSISTING OF EXPERIMENTALLY INDUCED, ACUTE CHOLESTASIS. IV: ALKALINE PHOSPHATASE. (It.) Zangrando, O. (U. Padua, Italy), G. Segato, G. Mantovani Orsetti and G. Rosa. Acta Chir. Ital. 21(6):1003-1010, 1965.

In dogs, ligation of the common bile duct was followed by an almost immediate, progressive increase of serum alkaline phosphatase activity, continuing throughout a 6-hr. observation period. This was accompanied by a progressive decrease of thoracic lymphatic alkaline phosphatase activity and an increase of liver alkaline phosphatase activity beginning after 2 hr. of very slightly decreased values. The mean differences observed were statistically significant at 6, 4 and 6 hr., resp., although an analysis of variance confirmed significance considerably earlier. It is concluded that the enzyme, which was produced by the liver cells and passed into the obstructed biliary passage, was reabsorbed rapidly through the venous circulation, while the relatively limited ability of lymph to absorb the same substance directly was reflected by the progressive diminution of activity in lymph derived from the thoracic region. An analogous phenomenon was observed with respect to bilirubin, a substance which is characterized by preferential absorption through the lymphatic system. Serum bilirubin levels were essentially unchanged during the progressive increase of serum alkaline phosphatase activity, but thoracic lymphatic bilirubin levels increased progressively as alkaline phosphatase levels were diminished in lymph derived from this region.

11608 THE HEPATIC LYMPHATIC SYSTEM IN THE PRESENCE OF PHYSICAL PATHOLOGY CONSISTING OF EXPERIMENTALLY INDUCED, ACUTE CHOLESTASIS. V: TRANSAMINASES. (It.) Zangrando, O. (U. Padua, Italy), G. Mantovani Orsetti, G. Rosa and G. Segato. Acta Chir. Ital. 21(6):1011-1020, 1965.

In dogs, ligation of the common bile duct was followed by progressive increase of serum glutamic-oxaloacetic and serum glutamic-pyruvic transaminase activity during a 6-hr. observation period, accompanied by a similar increase of the activity of

LIVER AND BILIARY TRACT

th substances in the lymph of the liver and the thoracic region. Although the results were reproducible, the changes in question were not marked and did not reach levels of statistical significance. Fluctuations were sufficiently limited that the ratio between the 2 substances was not inverted, despite a transient tendency toward diminution of serum glutamic-oxaloacetic transaminase activity, thoracic lymphatic glutamic-pyruvic transaminase activity and the liver lymphatic activity of both substances, during the first hr. after ligation. It is concluded that liver cellular damage did not occur in these animals during the first 6 hr. after ligation of the common bile duct and that the changes observed should be ascribed to the regurgitation of both enzymes from the obstructed biliary tract.

- 09 PATHOLOGICAL SULFOBROMOPHTHALEIN TEST IN EXTRA-HEPATIC DISEASES WITH SECONDARY INVOLVEMENT OF THE LIVER. (Ger.) Bargon, G. (U. Giessen, Germany) and C. Hochmiller. Acta Hepatosplen. 13(4):201-207, 1966.

Analysis of 327 cases of abdominal disorders associated with pathological sulFOBromophthalein excretion showed that in 286 the disturbance of liver function was due to liver disease (chronic hepatitis, cirrhosis, fatty degeneration), while in extrahepatic disorders with secondary involvement of the liver were responsible. These included diseases of the biliary tract (8), gastrointestinal disturbances (12), leukoidosis (4), and liver metastases from carcinomas of various sites (17). The underlying pathophysiological mechanisms are discussed.

- 10 THE TREATMENT OF CHRONIC LIVER DISEASE WITH A HIGH-DOSAGE VITAMIN B₁₂-FOLIC ACID PREPARATION. (Ger.) Hoffmann, F. X. (Niederrhein Sanatorium, Bad Neuenahr, Germany). Landarzt 42(23):1018-1021, 1966.

Agri-sevit forte, a combination of vitamin B₁₂ and folic acid, was given to 95 patients, aged 30 to 64 yr., with chronic liver disease. Diagnoses included chronic hepatitis (54), fatty liver (4), cirrhosis (9), secondary liver disease associated with stomach resection or chronic ulcer (19), and posthepatitis syndrome. Duration of treatment (dosage not stated) ranged from 6-12 wk. Subjective improvement was obtained in most cases within 1 wk. Objectively, secondary liver diseases responded best (10 of 19 improved markedly in 6-9 wk.); 3 of 9 patients with liver cirrhosis, 2 of 4 with fatty liver, and 9 of 9 with posthepatitis syndrome also showed significant improvement. In the group with chronic hepatitis, however, only 7 of 54 showed marked, 16 of 54 partial, and 31 of 54 no improvement. This is attributed to the short duration of treatment.

- 11 LIGHT- AND ELECTRON MICROSCOPIC FINDINGS OF THE LIVER IN INFANT TOXICOSIS. (Ger.) Heber, J. (Karl Marx U., Leipzig) and L. Cossel. Frankfurt. Zschr. Path. 75(3):243-251, 1966.

Liver biopsy material from 5 infants with toxicosis was examined by light and electron microscopy. Epithelial and endothelial cell nuclei and cytoplasm generally showed non-specific morphological evidence of increased metabolic activity. Less frequently, marked vacuolization of liver epithelium was observed. Fatty change was seen in 2 cases, incipient colliquative necrosis in one. Abnormal findings in predominantly normal mitochondria included circular arrangement of the internal membranes, occurrence of osmiophilic bodies, and diffuse or focal clearing of the matrix.

- 12 ORTHOTOPIC LIVER HOMOTRANSPLANTATION IN DOGS AFTER PROLONGED PERFUSION AT LOW TEMPERATURES. (Fr.) Kestens, P. J., P. Mikaeloff, J. H. Haxhe, G. Dureau, A. Alexandre, J. P. Rassat, J. Cuilleret, A. Hassoun, M. Dubernard, P. Maldague, J. Descotes and J. Morelle. Acta Chir. Belg. 65(2):197-213, 1966.

Cooled dog livers were placed in a perfusion apparatus at 4°C, and their blood vessels sutured to those of completely hepatectomized recipient dogs for 90-328 min. perfusion at 12-18°C. The recipient dogs were then reimplanted with their own livers. Immunosuppressive treatment of the recipients consisted of local irradiation (50 r) and actinomycin C during rejection crises; other treatment included azathioprine (in all dogs) and azaserine from days 15-30 after transplantation. All livers functioned normally during perfusion. Homeostasis during reimplantation was

LIVER AND BILIARY TRACT

satisfactory in all but 1 animal. Blood ammonia and lactic acid levels were elevated during the operation, but decreased when the grafted livers were re-established in the circulation. Transaminases and lactic dehydrogenases were moderately elevated. Sulfobromophthalein retention, studied in 3 dogs, was 5%, 19%, and 22% after 45 min. Four dogs died within 1 wk. and 2 within 13 days; 3 others survived 26-35 days, and 2 dogs survived for 93 and 117 days. In the 2 longest survivors, a moderate fever and a definite increase in serum transaminases were noted; the WBC was greatly increased (sometimes over 40,000) unless controlled by irradiation. One of these dogs showed almost complete pancreatic atrophy at autopsy; the other showed acute pyelonephritis.

- 11613 HEPATOMEGALY IN INFANCY AND CHILDHOOD: A CLINICOPATHOLOGICAL STUDY OF 98 CASES. (E.) Dayal, R. S. (S. N. Med. Coll., Agra, India), G. P. Mathur, R. Prasad and P. N. Wahi. Indian Pediat. 3(4):129-138, 1966.

In 98 infants and children (age 2 mo.-12 yr.; 53% were 1-3 yr. old; 63 male, 35 female) with hepatomegaly, the clinical, laboratory, and histopathological diagnosis was infantile liver cirrhosis in 42 cases, malnutrition with or without tuberculosis in 44 cases, obstructive jaundice, amebic hepatitis, or neonatal hepatitis in 2 cases each, infectious hepatitis, congenital biliary atresia, inspissated bile syndrome, gargoylism, liver abscess, or infectious mononucleosis in 1 case each. Laboratory data such as plasma protein levels, thymol turbidity, and flocculation tests, were not helpful in diagnosing these conditions. Tuberculous granuloma of the liver was seen in 1 of 27 cases of tuberculosis, and reactive hepatitis was only found in cases of tuberculosis. A marasmic appearance was always found in cases of malnutrition with or without tuberculosis. No case of malnutrition showed histological findings of cirrhosis. In cases of infantile cirrhosis, no fatty change was found; this confirmed the viewpoint that malnutrition as such is not related to liver cirrhosis.

- 11614 AMOEBIC LIVER ABSCESS DRAINING INTO THE BILE DUCTS. (E.) Viana, R. L. (Med. Res. Inst., Lourenço Marques, Mozambique). Gut 7(3):285-287, 1966.

Of 15 patients in whom amebic abscess was visualized fluoroscopically with contrast medium, 2 were shown to have spontaneous drainage of the liver amebic abscess into the biliary tree indicating that this condition is not as rare as previously considered. The 2 cases were both Bantu men, ages 19 and 26, who had enlarged livers and visible swelling in the right upper quadrant of the abdomen. Both patients presented with weakness, fever, right upper quadrant abdominal pain and signs of jaundice. In one, ova of Schistosoma haematobium was found in the urine and numerous ova of Ascaris lumbricoides as well as a few ova of T. trichiura and E. vermicularis were found in the feces. In the other case, the urine was normal but ova of T. trichiura and A. lumbricoides were found in the feces. In both cases the so-called "anchovy sauce" pus which is characteristic of a liver amebic abscess was aspirated by liver puncture. Response was rapid following anti-amebic treatment with chloroquine (0.6 g/day) and oxytetracycline (125 mg inj. into the abscess cavity). If the use of contrast medium for visualization of amebic liver abscess became routine, it is probable that more cases of spontaneous drainage would be seen and unnecessary multiple punctures or surgical drainage would be avoided.

- 11615 FATTY LIVER ASSOCIATED WITH ADMINISTRATION OF TETRACYCLINE IN PREGNANT AND NONPREGNANT WOMEN. (E.) Schiffer, M. A. (Jewish Hosp., Brooklyn, New York). Am. J. Obstet. Gynec. 96(3):326-332, 1966.

The case histories of 6 women (2 of whom were pregnant) who developed acute fatty metamorphosis of the liver in association with the admin. of tetracycline are reviewed to illustrate the similarity of their condition to that of Sheehan's syndrome. The 4 women who were not pregnant, ages 50-69 yr., received tetracycline i.v. in the course of treatment and all had elevated blood urea. Three underwent surgery (gastrectomy, cholecystectomy and sigmoid and bladder resection) and the fourth was admin. the tetracycline for pancreatitis. Renal failure, manifested by oliguria or high blood urea nitrogen, shock and intestinal bleeding ensued with eventual death. The pathological features were very similar to those in obstetric acute fatty metamorphosis. In the case of the 2 pregnant women, one followed this same moribund

ER AND BILIARY TRACT

tern, while the other, when the admin. of tetracycline was stopped, eventually overed. Both suffered hemorrhage of the gastrointestinal tract, as well as ndice, oliguria and increased blood urea nitrogen. The reversibility of the drome seems to depend on early suspicion and diagnosis (which requires a liver psy). It would seem that the use of this drug, especially parenterally, should restricted with pregnancy or acute surgical conditions as these 2 factors seem act as sensitizing agents on the liver.

- 16 AVENUES OF FUTURE RESEARCH IN HOMOTRANSPLANTATION OF THE LIVER. WITH PARTICULAR REFERENCE TO HEPATIC SUPPORTIVE PROCEDURES, ANTILYMPHOCYTE SERUM, AND TISSUE TYPING. (E.) Starzl, T. E. (U. Colorado Sch. Med., Denver), T. L. Marchioro, T. D. Faris, R. J. McCardle and Y. Iwaski. Am. J. Surg. 112(3):391-400, 1966.

periments with dogs using antilymphocyte serum or plasma after transplantation of liver indicate that prolongation of viability can be obtained with this organ. av. survival time in 8 dogs treated with horse antilymphocyte plasma was 15.6 s, while the av. survival time for 22 untreated dogs was 7.1 days. In addition, f the treated dogs which had not received any antilymphocyte serum after 3 wk. tinued to do well 2.5 mo. postoperatively. Another dog, pretreated with anti-phocyte serum has lived 6 wk. after an orthotopic liver transplantation: this mal received no postoperative treatment. In addition, orthotopic liver trans-plantation was performed on 4 dogs which had been treated solely with concentrated ma globulin purified from horse antilymphocytic serum and 3 were in their fourth toperative wk. (at publication). In addition to these promising results of unosuppression with liver transplants, the possible use of antigen matching nnics as an advanced indicator of donor-recipient histocompatibility is discussed terms of successes obtained with human renal transplants. A third point dis- sed in this paper was the prospects of obtaining temporary liver support with an racorporeal liver transplantation. Experiments with 6 dogs indicated that liver ction and survival time improved with this technic, but the results of this nnic with 2 patients dying with hepatitis were disappointing.

- 7 METABOLIC RESPONSES DURING EXPERIMENTAL HEPATECTOMY AS RELATED TO SUBSEQUENT PERFUSION, PRESERVATION, OR TRANSPLANTATION. (E.) Norman, J. C. (Harvard Med. Sch., Boston), W. G. M. Hardison, V. Covelli and W. V. McDermott, Jr. Am. J. Surg. 112(3):407-411, 1966.

surement of the pH, pO₂ and pCO₂ of hepatic afferent and efferent blood samples, well as measurement of liver slice ATP conc. and O₂ consumption, before and after eurement of the porcine liver showed that the functional viability and metabolic ential of the organ decreased during the procedure. The pigs were ventilated n 100% O₂ which induced an initial mild, systemic respiratory alkalosis. Despite s, and the routine infusion of 1 liter of Hartmann's soln., the overall metabolic onses to the procedure resulted in a final av. systemic pH of 7.45. During removal of the liver, which took an av. of 100 min., the portal vein pH de-ased and the pCO₂ increased nearly 25%. These changes probably had both an intra-extrahepatic source: the first, from vasospastic ischemia produced by afferent erial manipulation and dissection and, the second, from evisceration and angula- n of the small intestine with consequential torsion and angulation of splanchnic erial inflow. The measurements on the hepatic venous blood reflected increasing rahepatic hypoxia and metabolic acidosis. In addition, quantitative indication rgan deterioration was noted in that liver O₂ consumption decreased 32% and liver conc. decreased 63%.

- 8 AN EVALUATION OF 51 PATIENTS WITH HEPATIC ARTERY INFUSION. (E.) Rochlin, D. B. (U. California Sch. Med., Los Angeles) and C. R. Smart. Surg. Gynec. Obstet. 123(3):535-538, 1966.

hepatic arterial infusion was performed by 2 methods: (1) placement of a catheter percutaneous arteriotomy through either the brachial or femoral artery guided by roscopy through the celiac artery into the hepatic artery. (2) the direct rative placement of a catheter into the hepatic artery through a smaller side nch such as the right hepatic artery. There are advantages to each method. A

LIVER AND BILIARY TRACT

number of different agents can be admin. by these routes. The agent used in 43 of 51 cases was fluorouracil because the hepatic tumors in these instances were metastatic carcinomas against which this agent has been found effective in systemic infusions. A treatment regimen with fluorouracil, whether by open or closed technic, consisted of daily admin. of 10 mg/kg body wt. Therapy was continued for a minimum of 2 wk. unless severe toxicity ensued. Severe stomatitis, hematopoietic depression, or a rise in serum glutamic-oxalacetic transaminase has been used as the endpoint of therapy. After toxicity has disappeared, a weekly maintenance dosage of 10-15 mg/kg body wt. is inj. i.v. A total of 18 patients or 36% showed evidence of at least a 50% decrease in size of the measured masses following hepatic artery infusion. Of the evaluable cases treated, 44% showed objective evidence of response. In 22 evaluable patients who were treated for metastatic carcinoma of the colon, 12 showed evidence of a positive response by the criteria of remission used.

11619 ABDOMINAL ARTERIAL MURMURS IN LIVER DISEASE. (E.) Clain, D. (Royal Free Hosp., London), K. Wartnaby and S. Sherlock. Lancet 2(7462):516-519, 1966.

A total of 9 patients, 6 with microscopically confirmed hepatoma, 2 with alcoholic hepatitis and cirrhosis of the liver, and 1 with alcoholic hepatitis only, were found to have arterial murmurs over the liver, harsh in character and readily distinguished from a venous hum. In 2 patients the murmur was continuous with systolic accentuation; in 4 instances it was purely systolic. The murmurs were loudest over the liver except in one hepatitis patient where it was equally intense over the epigastrium, the ribs, and the liver. In 5 subjects the murmur was loudest over the hepatoma; this was verified by arteriography or isotope scanning. The tumor was in the right lobe in 2 cases and in the left lobe in 3. There were no distinguishing differences between the murmurs in alcoholic hepatitis and in hepatoma. The bruits were not conducted from other parts of the abdomen or from the heart; this was verified by sound recordings taken in 2 cases over the liver and the precordium. Posture, respiration and local pressure had no significant effect on the murmurs.

11620 SERUM 5'-NUCLEOTIDASE IN PATIENTS WITH TUMOR IN THE LIVER. (E.) Smith, K. (Baylor U. Med. Ctr., Dallas, Tex.), H. H. Varon, G. J. Race, D. L. Paulson, H. C. Urschel and J. T. Mallams. Cancer 19(9):1281-1285, 1966.

One group of 11 patients with histological diagnosis of liver tumor were tested for serum levels of 5'-nucleotidase (N) and alkaline phosphatase (AP). Normal range for N was 0.0-1.6 U, for AP 0.0 to 4 Bodansky units. N was elevated in each of the 11 patients from 2-20 times the normal value. In only 6 of 11 patients was the serum AP elevated and the increase was smaller than that of N; in only 2 cases was the increase more than twice the upper normal limit. In another group of 6 patients with an unequivocal isotope liver scan for metastatic tumor, but no biopsy, both enzymes were elevated in 2 cases, only N was elevated in 3 subjects and in 1 patient neither enzyme was elevated. Leucine aminopeptidase was assayed in 5 of the 11 proved cases but was within normal limits in all 5. The data suggest that serum N shows a greater sensitivity than serum AP in the detection of primary, or metastatic liver malignancy in the anicteric patient.

11621 FUNCTIONAL STATE OF THE LIVER IN CONNECTION WITH AGING. (Rus.) Smolyansk B. L. (Sanit.-Hyg. Res. Inst., Leningrad) and V. N. Kolmakov. Klin. Med. (Moskva) 44(6):53-57, 1966.

In 248 aged subjects (167 women and 81 men; age 60-90 yr.) without clinical liver diseases, disturbances in various liver functions which progressed with increasing age were seen. Serum bilirubin (studied in 180 persons) was normal (0.2-1 mg%). Hippuric acid excretion 4 hr. after loading was 70-90% in 129 of 173 persons and below 60-90% in 44 others; in 83.6% of the group, hippuric acid secretion reached max. values in the first 2 hr. The fluctuation between max. and minimal values of urinary specific wt. in various fractions decreased to 8-11 degrees, compared to a normal 12-16 degrees. Blood proteins (studied in 200 persons) were normal in the 60-80 age range, but the older subjects (80-90 yr.) showed hypoproteinemia; serum albumin (44.7-49.2%) was markedly decreased, while the increase in serum globulins was mostly due to an increase in the α_2 - and γ -globulins (by over 15% and over 25%, resp.). Serum cholesterol content was over 250 mg% in 18.5% of the

R AND BILIARY TRACT

up; the lecithin/cholesterol ratio fell to 0.7-0.9 in 12.5% of the subjects studied. The lipoprotein ratio was normal in 75.5%. Blood sugar content (studied in 100 persons) was normal in 84.5%, increased in 8%, and decreased in 7.5%. The arglycemic coefficient was increased in 58%, normal in 28.5%, and decreased in 13.5%; the postglycemic coefficient was increased in 62.5%, normal in 20%, and decreased in 17.5%. Serum carbohydrate metabolism was abnormal in 83.5% of 200 subjects studied. Glycemic curves after galactose loading were similar to those obtained after the glucose test. The prothrombin index was normal in 62.3% of 196 subjects studied; it was increased in 7.1%, and decreased in 30.6%. Liver cholesterol esterification was insignificantly disturbed in 84 patients studied (57.2% compared to normal of 50-70%). Glutamic-oxalacetic transaminase activity was situated between 8-40 U, compared to normal values of 5-40 U. These changes in liver function were due not only to age, but also to atherosclerosis.

2 SURGICAL ASPECTS AND TREATMENT OF ACUTE INTERMITTENT PORPHYRIA. (Pol.)

Klawe, Z. (Inst. Hemat., Warsaw, Poland) and T. Darocha. Pol. Tyg. Lek. 21(24-25):937-940, 1966.

Patients with acute intermittent porphyria, abdominal surgery was usually performed for other diseases, or as a consequence of inaccurate diagnosis, but on admission it was performed when the disease had been accurately identified by the von-Schwartz test for urinary porphobilinogen. Postoperative treatment during 1 wk. of observation consisted of morphine, chlorpromazine, and adenosine monophosphate. Of the authors' 25 patients, 20 had obvious symptoms of acute intermittent porphyria (1-3 full attacks had occurred in 17 cases; the other 3 had long histories of periodic pain). The characteristic lesions appeared in 12 patients; in 8 cases they appeared following surgery. Respiratory symptoms were seen in 7 patients, 6 of whom died. Five patients were treated by exchange transfusions, 3 of these patients also received adenosine monophosphate (150-200 mg/day); all patients showed clinical improvement and 4 also showed a reduction in urinary uroporphyrin excretion. A clinical and biochemical remission was followed by relapse and death in 1 patient.

3 PROTEINOGENIC AND PROTHROMBINOGENIC FUNCTION OF THE LIVER IN DYING AND REVIVAL OF THE ORGANISM. (Rus.)

Shapiro, V. M. (Lab. Exp. Physiol. Resuscitation, Acad. Med. Sci. USSR, Moscow). Pat. Fiziol. Eksp. Ter. 10(3):32-36, 1966.

Dogs killed rapidly (in 3-5 min.) by an electric current, there was no change in the total proteins of the arterial blood or hepatic vein blood, and the protein concentrations and prothrombin time were also unchanged. Prolonged bloodletting (90 min at least in 1 animal) resulted in a marked decrease in total protein in the hepatic vein and arterial blood, but there was no disturbance in the prothrombinogenic function of the liver. After the animals were revived (by blood transfusions, epinephrine, heart massage, and artificial respiration), the blood protein levels were restored, but hypoalbuminemia and an increase in α -globulin were noted, especially in blood from the hepatic vein. The prothrombinogenic function of the liver was also depressed, as shown by the decrease in prothrombin levels, especially in the hepatic vein blood. In 1 dog revived after 1.5 hr. of hypotension, total protein levels before and after resuscitation and 2 wk. later were 6.10%, 6.64%, 5.81%, resp., in the arterial blood, compared to 5.97%, 6.70%, and 5.47%, resp., in the hepatic venous blood. Albumin content in the arterial blood at these times was 35%, 32%, and 34%, resp., compared to 38%, 36%, and 29%, resp., in the hepatic venous blood. The α -globulin conc. at these times was 18%, 21%, and 24%, resp., in the arterial blood, compared to 17%, 20%, and 24%, resp., in the hepatic venous blood.

4 EXPERIMENTAL STUDIES ON EXTENSIVE HEPATECTOMY, WITH SPECIAL REFERENCE TO THE PATHOHISTOLOGICAL CHANGES AFTER PORTAL OCCLUSION AND HEPATECTOMY. (Jap.)

Enzan, M. (Osaka Coll. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 34(6):1582-1610, 1965.

Portal vein ligation for 30 min. caused histological changes (severe congestion in spleen and small intestine, with a marked decrease in liver glycogen) indicating

LIVER AND BILIARY TRACT

severe liver anoxia and blood stagnation in the portal system in dogs. These changes were reduced if the superior mesenteric artery was simultaneously ligated, but only if this occlusion lasted 30 min.; after 60 min. of occlusion of 1 or both blood vessels, the anoxic changes were similar. There were no apparent histological differences in the livers of dogs undergoing portal vein ligation under normothermic or hypothermic conditions, but less damage to the mitochondria, cytoplasm, and nucleus was noted under the electron microscope in the latter group. A technic for hepatectomy, using a crimped dacron tube encircling the liver at the site of subsequent resection, is described. When 50% hepatectomy was performed by this method, the encircled and compressed portion of the liver stump became necrotic after 2 wk. and was replaced by granulation tissue and fibrosis after 2 mo. There was no biliary leakage or oozing from the stump up to 3 mo. after resection. This technic of hepatectomy, with simultaneous occlusion of the portal vein and superior mesenteric artery under hypothermia (below 30° C), is recommended for control of oozing and biliary leakage from the cut surface of the liver.

- 11625 EXPERIMENTAL STUDIES ON TEMPORARY HEPATIC AFFERENT VASCULAR OCCLUSION WITH EXTRACORPOREAL CIRCULATION OF THE PORTAL VEIN. (Jap.) Kato, K. (Kyoto U. Sch. Med., Japan). Nippon Geka Hokan (Arch. Jap. Chir.) 35(2):346-362, 1966.

Dogs with temporary occlusion of the portal vein and hepatic artery showed no drop in blood pressure or splanchnic pooling if extracorporeal circulation was employed; after prolonged (40 min.) occlusion, the survival rate was 78% (7 of 9). When the blood vessels were occluded for 40 min. and a portal-femoral vein bypass was added, the survival rate was 63%. Simple occlusion for 20 min. resulted in a survival rate of 84%, but 30 min. of occlusion was fatal to all animals. The causes of early death in all 3 groups were shock and hypotension following release of the occlusion, probably resulting from severe disturbance in the liver circulation due to pooling of large amounts of blood in the liver after release of occlusion, and the effect of a vasodepressor substance liberated from the anoxic liver. The survival rate increased as the room temperature and the liver temperature decreased, although hypothermic conditions were not employed in this study. Total serum bilirubin and sulfobromophthalein retention tests indicated a slight degree of liver damage, but serum transaminases increased markedly (max. 500-600 U after 12 hr., with normalization after 1 wk.); temporary hypoglycemia was seen immediately after release of the occlusion in all dogs. Histological changes in the liver following release of the occlusion demonstrated dilation and congestion of the sinusoids. Marked necrosis and acute red atrophy of the liver were seen after 12 hr. in fatal cases, together with temporary degenerative changes in the kidneys. Dogs undergoing 50% hepatectomy under a 30-min. occlusion of the portal vein and hepatic arteries, with extracorporeal circulation of the portal vein, remained in good condition before and after surgery, with only slight bleeding from the cut surfaces of the liver.

- 11626 EVALUATION OF JIRGL'S TEST AND OTHER LIPOPROTEIN TESTS IN THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE. (Pol.) Szymanska, H. (2nd Clin. Intern. Med., Polish Acad. Med., Szczecin), A. Nieczajew and H. Myśliwicz-Rychlik. Pol. Arch. Med. Wewnet. 36(5):667-673, 1966.

Jirgl's β -lipoprotein test was positive in 67.4% (83) and negative in 32.6% (40) of 123 patients with obstructive jaundice due to gallstones (59) or malignant disease (64); it usually became negative when jaundice was corrected. There was no correlation between the results of Jirgl's test (graded as negative to 3+) and bilirubin levels or the duration of jaundice. Jirgl's test was negative in 83.9% (181) of 216 patients with viral hepatitis; it was slightly positive to positive in 10.6% (23 cases), and marked in 12 cases (5.5%) only during the period of abnormal serum bilirubin levels. Patients with obstructive jaundice and positive Jirgl's tests also showed elevated levels of β -lipoproteins, seromucoids, β -globulins, α -lipid fractions, and cholesterol esters, with decreased levels of β -lipids, cholesterol, and thymol turbidity. Patients with viral hepatitis and positive Jirgl's tests showed increased values for β -lipoproteins, β -globulins, β -lipid fractions, cholesterol, cholesterol esters, and thymol turbidity; seromucoids and

R AND BILIARY TRACT

pid fractions were decreased. Jirgl's test was also performed in 125 controls, which included patients with gallstones or malignant disease without jaundice; a slightly positive test was noted in only 1 of these cases (with gallstones). It is concluded that Jirgl's test, although not satisfactorily sensitive, is a valuable differential diagnostic method in jaundice.

7 STUDIES ON PLASMIN IN THE LIVER TISSUE AND PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC LIVER DISEASE. (Jap.) Terada, H. (Osaka City U. Sch. Med., Japan). Osaka Shiritsu Daigaku Igakubu Zasshi (J. Osaka City Med. Ctr.) 14(7-9):447-470, 1965.

The fibrinolytic activity was measured by the Astrup fibrin plate method, using liver biopsy specimens from 40 patients with cirrhosis (21), acute hepatitis (6) and chronic hepatitis (13). The size of the area of lysis on the standard fibrin plate was largest in cirrhosis, followed by chronic and acute hepatitis (in that order); fibrinolytic activity was destroyed by heat in all cases, and almost completely inhibited by ϵ -aminocaproic acid. Tissue plasminogen activator seemed to increase parallel to the extent of liver fibrosis. A significant correlation between liver tissue activator levels and fibrinolytic activity of the peripheral blood was noted in patients with cirrhosis; there was also a statistically significant correlation with the albumin:globulin ratio. Similar results were also seen in experiments with liver fibrosis produced by the Campbell method.

Hepatic Injury

- 717 STIMULATION OF HEPATIC MICROSOMAL DRUG-METABOLIZING ENZYME SYSTEMS IN PRIMATES BY DDT. (E.) Juchau, M. R. (U. Iowa Sch. Med., Iowa City), T. E. Gram and J. R. Fouts. *Gastroenterology* 51(2):213-218, 1966.

It is known that the metabolism by hepatic microsomes of several drugs can be stimulated in rats by a number of halogenated hydrocarbon insecticides, including DDT and chlordane. The authors were interested whether this situation obtains also in man. Preliminary studies indicated that chlordane increased liver microsomal enzyme activity in the squirrel monkey. Although both chlordane and DDT stimulated liver drug metabolism in rats, only chlordane had this effect in mice. Studies were made on the effect of DDT on liver microsomal metabolism of a number of drug substrates. Experimental squirrel monkeys received 5 mg of DDT/kg/day or 10 mg of DDT/kg/day for 7 days by i.p. inj. in corn oil, while control monkeys received the corn oil only. *In vitro* measurements indicated increased liver microsomal metabolism of aminopyrine, p-nitrobenzoic acid, and zoxazolamine, and, to a lesser extent, metabolism of 3,4-benzopyrene and hexobarbital. There was no statistical difference between the 5- and 10-mg/kg/day regimens. A further study with 10 and 20-mg/kg/day regimens showed the 5 mg admin. to exhibit max. effect. Pretreatment with DDT also increased the microsomal oxidase activity of NADPH (reduced nicotinamide adenine dinucleotide phosphate). The amount of liver microsomal cytochrome C₁₀-binding pigment was also increased. It is postulated that these increases are indicative of involvement in the induction of drug-metabolizing enzymes. In animals receiving 10 mg/kg/day of DDT there was no significant change in liver wt., total animal wt., or nitrogen content of the 9000 g supernatant fraction compared with controls. Monkeys receiving 10 and 20 mg/kg/day exhibited increased liver wt. and nitrogen content of the 9000 g supernatant fraction and decreased total body wt., as compared with controls.

- 718 THE EFFECT OF DIET AND 1,1,1-TRICHLORO-2,2-bis-(p-CHLOROPHENYL)ETHANE (DDT) ON MICROSOMAL HYDROXYLATING ENZYMES AND ON SENSITIVITY OF RATS TO CARBON TETRACHLORIDE POISONING. (E.) McLean, A. E. M. (Royal Free Hosp., London) and E. K. McLean. *Biochem. J.* 100(2):564-571, 1966.
- Star-derived Porton strain rats, fed on a protein-free diet, showed an oral LD₅₀ of 14.7 ml/kg for carbon tetrachloride (CCl₄), whereas without the special diet, the LD₅₀ was 6.4 ml/kg, indicating that protein-depleted rats are resistant to the lethal effect of CCl₄. This was true despite the presence of a fatty liver. This protective effect was observed from 4 days of no-protein feedings onwards, after feeding rats on a 3%-casein diet and, partially, after a 6%-casein diet. At the same time, the activities of the liver microsomal enzymes that demethylate Pyramidon and hydroxylate benzopyrene fell by over 80% in those rats fed on either the no-protein diet or the 3%-casein one, and fell 50% in those fed on a 6%-casein diet. Therefore, the critical protein conc. in the diet for marked depression of microsomal hydroxylation enzymes lies between 3-6%. A single dose of DDT or 3 doses of phenobarbitone reversed this depression of microsomal activity. It also caused these animals on special diets to become more sensitive to CCl₄ toxicity, as well as those on stock diets. These estimations were determined by histology, accumulation of liver water and plasma enzyme and bilirubin measurements. They support the hypothesis that CCl₄ is metabolized by microsomal enzymes which require the hydroxylating enzymes to form the true toxic compound.

- 719 EFFECT OF DIETARY IRON ON GOSSYPOL TOXICITY AND ON RESIDUES OF GOSSYPOL IN PORCINE LIVER. (E.) Clawson, A. J. (North Carolina State U., Raleigh) and F. H. Smith. *J. Nutr.* 89(3):307-310, 1966.

A 3 x 3 factorial design was used to study 3 ration levels of free gossypol, ratios of added iron to free gossypol and 2 sources of supplemental lysine on the pig liver. Levels of 80, 244, and 400 mg of free gossypol/kg of diet were obtained from cottenseed meal. Iron was added as ferrous sulfate in wt. ratios of 0:1, 0.5:1 and 1:1 free gossypol. Pig performance was not adversely affected by 80 mg/kg of gossypol, and an iron to gossypol ratio of 1:1 protected the pigs from up to 400 mg/kg diet of gossypol. The iron/gossypol ratio prevented gossypol

accumulation in the liver in the excess of that observed when 80 mg/kg diet was fed. A 0.5:1 iron to gossypol ratio improved performance in the test animals but did not reduce toxicity or gossypol deposition in the liver as did the higher iron to gossypol ratios.

- 11720 THE PREVENTIVE EFFECTS OF NICOTINIC ACID AGAINST EXPERIMENTAL HEPATO-TOXICITY PRODUCED BY CARBON TETRACHLORIDE. (E.) Kamel, S. H. (Cairo U., Egypt), A. M. Elwi, H. El-Kateb and M. A. Soliman. *J. Egypt. Med. Assn.* 48(10):671-679, 1966.

In albino mice inj. i.p. with 50 mg nicotinic acid for 3 days and on the third day with CCl₄ (s.c.; 8 ml/kg body wt.), the mortality rate was 3.3% as compared to controls not inj. with nicotinic acid but receiving the same dosage of CCl₄, among which the mortality rate was 16.6%. At higher dosages of CCl₄ the mortality was as great among animals treated with nicotinic acid as among those not treated. Thus at levels of CCl₄ with 8 ml or less/kg body wt. nicotinic acid did exert a protective action against the tetrachloride. Liver cells showed degenerative changes which were milder than those of animals inj. with CCl₄ only. Necrosis was limited to the centrilobular areas and in the livers of the animals which received nicotinic acid there were hydropic cells with large nuclei and reticulated cytoplasm, an indication of reversal of degenerative changes. The protective action of nicotinic acid was extended to the kidneys where the glomerular congestion was much less severe than in animals not receiving this substance. Round-cell infiltration was less in nicotinic acid-treated animals.

- 11721 VITAMIN C AS A PROPHYLACTIC DRUG AGAINST EXPERIMENTAL HEPATOTOXICITY. (E.) Soliman, M. A. (Cairo U., Egypt), A. M. Elwi, H. El-Kateb and S. H. Kamel. *J. Egypt. Med. Assn.* 48(11-12):806-812, 1966.

In a series of experiments, white mice were inj. i.v. with 30 mg of vitamin C each 30 min. prior to an inj. s.c. of CCl₄ in the amount of 8 ml/kg body wt. Controls received the same dosage of CCl₄ without vitamin C; the mortality rate for the controls was 16.6% and 0% for the animals which received vitamin C. With higher dosages of CCl₄ this protective action of vitamin C was not apparent. Vitamin C reduced hepatic necrosis to a narrow rim of centrilobular cells. The necrotic areas and the portal tracts were infiltrated by histiocytes and lymphocytic cells. Regenerative cells, large in size, were present in the centrilobular region. A few animals had mild congestion of glomeruli with some tubular degeneration and necrosis in relatively few tubules it seemed evident that the prophylactic activity of vitamin C was greater than that of vitamin E and that of nicotinic acid.

- 11722 LIVER CELL DAMAGE AND DRUG METABOLIZING ENZYMES. (E.) Remmer, H. (U. Tübingen, Germany). *Excerpta Med. (Int. Congr. Ser.)* (115):154-158, 1966.

The literature on the relationship of liver cell damage to the hepatic enzymes which metabolize drugs is reviewed following which the author presents the effects upon the ultrastructure of liver cells after admin. of very high doses of phenobarbital approaching the LD₅₀ levels. These changes in the endoplasmic reticulum were similar to the early damage observed in the liver after toxic injury due to CCl₄, butter yellow, allyl formate and other compounds. The tubules of the endoplasm were distended and had lost their ribosomal particles; the vesicles of the smooth endoplasmic reticulum were enlarged. When 80 mg/kg of phenobarbital had been inj. i.p. for 5 days and the liver cells were fixed 2 days after ending admin. of phenobarbital, a latticework of smooth tubules, which occupied the entire hyaloplasm of the liver cell, had grown out of the ergastoplasm or rough membranes. The liver changes seemed to be reversible. If the rat recovered from such high doses of phenobarbital, a period of considerable enzyme induction ensued.

- 11723 THE ROLE OF MICROBIAL FLORA IN THE HEPATOTOXICITY OF CHLORTETRACYCLINE IN VIVO: A STUDY WITH GERM-FREE MICE. (E.) Einheber, A. (Georgetown U. Sch. Med., Washington, D. C.), H. Rosen, R. E. Wren and N. N. Beaudry. *Biochem. Pharmacol.* 15(8):1093-1104, 1966.

Experiments on the hepatotoxicity of chlortetracycline (CTC) in vivo were made using germ-free (GF) mice and mice which had been germ-free (GF) but were

conventionalized" (CONV), i.e., purposely contaminated with cecal material from conventionally-reared mice. The mice were handled and monitored microbiologically, maintained in isolation, fed a steam-sterilized diet, and exposed to an alternating 12-hr. schedule of alternating illumination and darkness. In the first experiment CTC was inj. i.p. at a dose of 100 mg/kg body wt., with controls receiving an equivalent vol. of saline. The dosage was repeated once daily for 4 consecutive days. Animals were killed 24 hr. after the last inj., and the livers studied for histology, water content, and for lipid analysis. Total lipids were extracted, separated by chromatography and total glycerides analyzed by infrared. In the second experiment, liver glycogen and protein were quantitatively determined. Liver transaminases (GOT and GPT) were assayed as well as glutamic dehydrogenase (GDH). Experiment 3 was the same as Experiment 2 with the exception that the animals had been fasted for 4 days prior to the actual experiment. These studies revealed that CTC hepatotoxicity is primary, i.e., it does not depend upon changes induced in the intestinal flora but is the result of direct action upon the liver. The changes in GF and CONV animals were similar and in the same direction. In fact, the effects seemed to be exaggerated in the GF mice. The following increased: liver wt., total lipids, and lipid fractions. Decreases occurred in: water content, protein, activity of the liver enzymes, GOT, GPT, GDH, urea cleavage enzyme, and aminase. Fasting increased the above effects. Untreated GF and CONV mice showed no significant differences when they were subjected to the same battery of analyses.

- 724 STUDIES ON THE HEPATOCYTE IN AZO DYE CARCINOGENESIS. (E.) Palekar, S. D. (Indian Cancer Res. Ctr., Bombay, India) and S. M. Sirsat. Indian J. Exp. Biol. 4(2):73-78, 1966.

Swiss mice (12 male and 12 female, wt. 21 g) were used to study the alterations produced in individual hepatocytes under the optical and electron microscope by dimethylaminoazobenzene (DAB). The diet used was a standard low protein riboflavin-deficient mixture with 0.06% of DAB (about 5 mg/day) dissolved in olive oil. The experimental animals averaged a 5% wt. loss during the first 3-4 wk. of DAB intake and recovered to gain wt. normally throughout the experiment. Animals were killed after 8-43 wk. of DAB feeding; 2 experimental and 2 control animals were killed at each time interval. Liver tissue was prepared for both types of microscopy. At 8 wk. it was possible to distinguish 2 morphologic types of cells. An abnormally large cell with dense cytoplasm showed increased basophilia; this type of cell had clumped chromatin, often with more than one nucleus/cell. The second type of cell exhibited a vacuolated cytoplasm and a comparatively large nucleus. The Schiff stain showed moderate amounts of glycogen in the dense cells; the cells with vacuolated cytoplasm showed little if any glycogen. Cytoplasm surrounding the nuclei of dense cells were deeply pyronine-positive. The electron microscope revealed cytoplasmic inclusions (scattered endoplasmic reticulum and ribosomes); mitochondria appeared more numerous than normal. Nucleoli were filamentous and there were often 2 nucleoli/nucleus. At 12 wk. the number of dense cells had increased; only an occasional cell was Schiff-positive. Nucleoli stained with positive dyes. The electron microscope showed an agranular cytoplasm. The nucleus at this stage had a normal appearance. At 16 wk. there were only occasional dense cells. Cytoplasm of most cells was vacuolated; many nuclei were deeply staining. The fine structure mitochondria were swollen. At wk. 22 the condition was further intensified with pyknotic nuclei. By wk. 43 hepatoma had been established with appearance of the dense cell type with dense nuclei.

- 725 REACTION OF DAMAGED LIVER IN EXPERIMENTAL CHOLEDOCHUS OCCLUSION. (Ger.) Vido, J. (Komensky U., Bratislava, Czechoslovakia), I. Vido and R. Moravec. Acta Hepatosplen. (Stuttgart) 13(4):228-232, 1966.

Serum bilirubin values and levels of glutamine-oxalacetic (SGOT) and -pyruvic (SGPT) transaminase, and alkaline phosphatase were measured in 8 mongrel dogs (10-25 kg body wt.) one day before, and 2, and 4 days after double ligature of the choledochus and resection of the portion between ligatures. Four of the dogs received 5 ml/kg CCl₄ twice within 11 days. The surgery was performed 40 days after the first CCl₄ admin., the dogs showing no more toxic symptoms at this time. The bilirubin values in mg% for the days 1 (before), 2, and 4 (after surgery) were, resp.,

0.71, 1.03, and 2.28 for the test animals, and 0.88, 0.81, and 3.32 for the controls. The alkaline phosphatase values (in King-Armstrong Units) were, resp., 9.5, 11.4, and 29.2 against 5.7, 10.7, and 40.2; SGOT values: 0.8, 1.4, and 2.50, against 0.62, 1.90 and 5.30; SGPT: 2.12, 2.82 and 19.0 against 0.82, 4.80 and 30.5. Only the difference in SGPT values between test and control animals was statistically significant. It appears, however, that the liver responses to the above acute choledochus occlusion were less pronounced in the group which suffered previous liver damage.

- 11726 EXPERIMENTAL STUDIES ON LIVER COENZYME A. II. COENZYME A AND PANTOTHENIC ACID LEVEL IN THE LIVER OF THE RATS TREATED WITH CARBON TETRACHLORIDE, DL-ETHIONINE OR PARTIALLY HEPATECTOMIZED. (E.) Kamematsu, Y. (Kyoto U. Fac. Med., Japan). Naika Hokan (Jap. Arch. Intern. Med.) 13(3):133-137, 1966.

Three hr. after the s.c. admin. of carbon tetrachloride (CCl_4 ; 0.1 ml/100 g of 10% soln.) to female Wistar rats, the liver conc. of Coenzyme A (CoA) was 12% less than the pre-injection level. The CoA conc. was minimal 24-48 hr. after inj., being 43% of the initial level. While the total pantothenic acid (PaA) conc. was practically unaltered by the admin. of the CCl_4 , 24 hr. after the inj., the ratio of bound PaA/total PaA had diminished from 0.78 to 0.49. Pre-inj. levels of these 2 components was not reached until about 10 days after the inj. When liver damage was induced by the admin. of DL-ethionine (a total dose of 75 mg), the CoA conc. decreased to 39% less than the initial conc. 48 hr. after the inj. When liver damage was CoA conc. returned to the initial level after 5 days. During this time the ratio of bound PaA/total PaA decreased slightly. When a partial hepatectomy was performed on rats, the liver CoA conc. decreased to 30% below the initial conc. and then returned to the initial level by postoperative day 7; there was little change in either the total or bound PaA conc. after surgery.

- 11727 LIPOTROPIC EFFECT OF BETAINE ASPARTATE ON EXPERIMENTAL HEPATIC STEATOSIS. STUDY WITH THE AID OF TRIOLEIN- C^{14} . (Fr.) Perrault, M. (St. Antoine Hosp., Paris, France) and Y. Dormard. Therapie 21(3):719-731, 1966.

Following a 30-day steatogenic diet, adult, male Wistar rats received betaine aspartate, 250 mg/kg/day, p.o. in distilled water, followed 30 days later by p.o. admin. of C^{14} -labeled triolein in olive oil, by esophageal sound. A statistically significant diminution of the loss of body wt. was seen in treated animals, as compared to untreated, steatogenic controls, and symptoms of hepatic steatosis were limited to a moderate degree of fatty infiltration of the cells, with some localized hemorrhaging. Steatogenic controls showed extensive hepatic tissue changes, extensive lysis of liver cells and numerous pyknotic nuclei. In treated animals, triolein- C^{14} clearance from the blood was much more rapid than it was in controls, where it was virtually totally blocked, and liver retention of triolein was significantly less. It is concluded that betaine aspartate exerted significant lipotropic and hepatoprotective activity against dietetically-induced hepatic steatosis in rats.

- 11728 HEMOPOIETIC COLONY-FORMING UNITS IN REGENERATING MOUSE LIVER: SUPPRESSION BY ANTICOAGULANTS. (E.) Varon, M. L. (U. S. Naval Radiol. Def. Lab., San Francisco, Cal.) and L. J. Cole. Science 153(3736):643-644, 1966.

After carbon tetrachloride-induced hepatic damage (s.c. inj. of 0.2 ml of 40% CCl_4) in homogeneous female mice, colony-forming units (presumably circulating peripheral blood WBC) localize in the liver and are trapped in the network of fibrin. This trapping mechanism is deduced by the fact that anticoagulant therapy with warfarin of sufficient dosage (a total of 11.28 mg in 4 days) to increase the normal prothrombin time 3.4-4.5 times inhibited this localization. The number of colony-forming units in the liver was determined by i.v. inj. of 20 mg of CCl_4 -treated liver tissue into recipient homogeneous mice, which had received 900 rad of whole-body X-irradiation within the previous 3 hr., and subsequent examination for macroscopic nodules in the spleens of these mice. Previously, it had been shown that the number of these spleen nodules is directly related to the number of colony-forming units

which were in the inj. liver. The i.v. inoculum of liver cells from mice previously inj. with CCl₄ contained approx. 8 times as many colony-forming units as control livers. The admin. of warfarin prevented this increase, while a concurrent admin. of vitamin K restored the increase. These data indicate that sites of extramedullary hemopoiesis might be adversely affected by anticoagulants.

729 INDIVIDUAL REACTION OF THE LIVER TO EXPERIMENTAL ADMINISTRATION OF CARBON TETRACHLORIDE. (E.) Vido, I. (Komensky U. Med. Fac., Bratislava, Czechoslovakia). *Med. Pharmacol. Exp. (Basel)* 14(6):550-556, 1966.

A group of 12 dogs which had been given carbon tetrachloride s.c. (0.3 ml/kg a 1:4 soln. every 4 days for 5 mo.), the sulfobromophthalein (BSP) retention and serum glutamic-pyruvic transaminase (GPT) activity in 2 dogs differed markedly from the rest. In these 2 animals the retention of BSP in serum was essentially lower than the mean value of the other 10: the difference in the values for the 2 groups was statistically significant. In these same 2 dogs, the activity of serum GPT was also relatively low: the mean value for the activity of GPT being 2.6 mM compared to 7.5 mM in the other 10 dogs. Also in the 2 dogs where the BSP retention and the serum GPT activity were low, the histologic picture at the end of the experiment did not show the following notable changes which were seen in the other 10 dogs: a centroacinar necrosis in resorption with marked steatosis and formation of balloon cells, as well as focal or diffuse fibrosis. Either genetic resistance acquired by some adaptive process is assumed in these 2 exceptional dogs.

730 THE INFLUENCE OF VENOUS AND ARTERIAL FLOW ON LIVER REGENERATION AFTER SUBTOTAL HEPATECTOMY IN RATS. (It.) Prete, F. (U. Bari, Italy), C. Chiumarulo, L. Consiglio and A. Leggio. *Gior. Ital. Chir.* 21(6):845-856, 1965.

Two groups of 20 rats underwent subtotal (68%) hepatectomy, accompanied by ligation of the splenic vein, the gastroduodenal vein, the superior mesenteric vein, the common hepatic artery or the proper hepatic artery, resp., while a control group underwent hepatectomy alone. Postoperative mortalities were 13.3%, 6.6%, 100%, 10%, 16% and 0%, resp. In most cases, sacrifice occurred 18 days after hepatectomy, and the grade formula for calculating regeneration percentages was used. Splenic vein and gastroduodenal vein ligation resulted in slight, transitory variations of hepatic regenerative capacity (98.8%-102.1%, as compared with 101.3% in controls after 18 days). No effect on regenerative capacity was exerted by ligation of the superior mesenteric vein. After ligation of the proper hepatic artery, only slight, but instant, reduction of hepatic regenerative capacity was noted, and no effect was exerted by ligation of the common hepatic artery. The degree of regeneration seen after ligation of the proper hepatic artery averaged 92.8%, as compared to a control value of 101.3%. It is concluded that these results appeared to contradict the theory held by many investigators concerning importance of blood flow in hepatic regeneration.

731 STUDY OF THE EFFECT OF CHLORPROMAZINE ON VARIOUS ENZYME SYSTEMS IN THE PLASMA AND LIVER OF THE RAT. (Fr.) Gielen, J. (U. Liège, Belgium). *Ann. Biol. Clin. (Paris)* 24(3-4):451-461, 1966.

Male rats weighing 250-300 g were divided into acute and chronic intoxication groups. The former received a single, 5-mg inj. of chlorpromazine, i.p. The other received inj. of 0.5 mg, s.c., at weekly intervals. In the acute intoxication group, no significant variations of serum fructose-1,6-diphosphoaldolase or serum glutamic-pyruvic transaminase were seen. Malic and isocitric dehydrogenase levels were somewhat increased, but not to as great a degree as those of glutamic-oxaloacetic transaminase, lactic dehydrogenase and ornithine carbamyl transferase. The isoenzymes of lactic dehydrogenase were separated by starch block electrophoresis, but were not found to be altered significantly. Hepatic levels of lactic dehydrogenase increased slightly during the first few hr. after inj. and again on day 4. No significant changes of serum enzyme levels were seen in the chronic intoxication group, though a consistent increase of an hepatic isoenzyme (fraction 5) of lactic dehydrogenase was observed during wk. 5-7, inclusive. It is indicated that individual variations of response among the treated animals were too great to permit drawing

reliable conclusions, although the increased level of the hepatic isoenzyme (above) in the presence of chronic intoxication may have been related to the intracellular hepatotoxic effects of chlorpromazine.

- 11732 EFFECT OF CARBON TETRACHLORIDE ON BLOOD GLUTATHIONE REDUCTASE ACTIVITY IN RABBITS. (E.) Cambosos, N. M. (Food & Drug Admin., Washington) and J. F. Reilly. *Toxic. Appl. Pharmacol.* 9(1):171-184, 1966.

When a single dose of 0.05 ml of carbon tetrachloride (CCl₄) was inj. into rabbits, a rise in whole blood and plasma glutathione reductase (GR) activity followed. If this dosage was admin. at monthly or biweekly intervals, the glutathione reductase levels rose to a higher value after each succeeding dose, yet between inj. the plasma and whole blood values of both groups returned to control levels. Up to the third inj. the RBC contribution did not change in the biweekly and monthly groups, indicating that the RBC did not contribute to the plasma values at that time. However, after the third inj. in the biweekly group, the RBC component was depressed, indicating that at this time the RBC had been damaged by CCl₄ and the RBC lost glutathione reductase into the plasma. When this dosage of CCl₄ was admin. on a weekly schedule, the plasma and whole blood glutathione reductase values failed to return to control levels between inj. and the portion of glutathione reductase delivered by the RBC to the whole blood glutathione reductase value decreased dramatically during this study, indicating that time between doses was insufficient for the hematopoietic system to replace damaged RBC or a depressed hematopoietic system. Bilirubin appeared in the blood only during daily admin. of this dose of CCl₄ and these were the only animals with apparent deterioration.

- 11733 EXPERIMENTAL STUDY ON THE WHITE RAT OF THE ANTISTEATOGENIC EFFECTS OF BETAINE ASPARTATE. (Fr.) Richir, Cl. (Fac. Med. Pharm., Dakar, Senegal), J. Cros and M. Martineaud. *Therapie* 21(3):711-718, 1966.

Four experimental and 2 control groups of rats received different diets: Group 1 (weighing 100 g) received a 72% high fat, protein containing diet, Group 2 (195 g) a 64% fat diet, Groups 3 and 4 were fed a high fat diet supplemented by 100 mg and 800 mg/kg/day doses of betaine aspartate. The control group received a balanced diet. Histologic examination, using Sudan Black technic, of the vital organs revealed a large number of small sudanophilic vacuoles and large vacuolated areas between the cells (macrosteatosis in 14 of the 22 rats). Microsteatosis was observed in 19 out of 20 rats. Treated animals showed a complete elimination of macrosteatogenic vacuoles while the serious cases of microsteatosis were reduced considerably. Dosage of 350-400 mg/kg/day was the most effective in protecting 8 out of 10 cases from steatosis and reducing the small vacuole conc. considerably.

- 11734 DELAYED HEPATITIS AND CIRRHOSIS IN WEANLING RATS FOLLOWING A SINGLE SMALL DOSE OF THE SENEIO ALKALOID, LASIOPARPINE. (E.) Nolan, J. P. (Yale U. Sch. Med., New Haven, Conn.), R. L. Scheic and G. Klatskin. *Am. J. Path.* 49(1):129-151, 1966.

A single small dose (80 mg/kg) of an aqueous soln. (pH 6.8) of lasiocarpine admin. by stomach tube to 127 21-day-old Wistar rats produced in 32 of 58 rats surviving after 9 days a delayed, progressive form of subacute or chronic hepatitis characterized by megalocytosis, focal necrosis, inflammation, nodular hyperplasia, ductular proliferation and fibrosis. An additional 20 survivors exhibited megalocytosis without other lesions. Wedge liver biopsies were obtained from 123 rats either on day 3 (108 rats) or day 9 (15 rats); 61 additional biopsy specimens obtained from 47 animals at intervals (day 9-47) and necropsy specimens from 29 animals sacrificed (day 35-160) and from the 98 rats that died during the experiment were examined. Acute hepatic necrosis was demonstrable in 28 of the 123 rats subjected to early biopsy, but in none of the 58 that survived 9 days or longer. Serial biopsies indicated that the acute necrosis occurred on or before the third day and healed without residuals during the following wk., whereas the delayed hepatic lesions appeared 2-3 wk. after lasiocarpine was admin. Only 5 of the rats that developed delayed hepatitis had exhibited necrosis on early biopsy. In 108 older (4 wk.) Sprague-Dawley rats given a larger dose of lasiocarpine (120 mg/kg) megalocytosis developed, but they failed to show any of the other features of the

Delayed lesion. Delayed lesions comparable in incidence and appearance to those shown by Wistar rats were produced by the same dosage (80 mg/kg) of lasiocarpine in 4-wk.-old male Sprague-Dawley rats maintained on two different stock diets. Attempts to recover bacteria, fungi, or a virus on culture of liver specimens or to transmit the disease to intact weanling rats by giving them a homogenate of pooled diseased livers were unsuccessful.

- 735 LIPASE ACTIVITY IN THE LIVERS OF DOGS AFTER ADMINISTRATION OF ETHIONINE. (Pol.) Torzecki, Z. (Inst. Path. Anat., Acad. Med., Lodz, Poland). Pat. Pol. 17(2):139-146, 1966.

Dogs treated with ethionine (doses not stated), hepatic lipase activity decreased and eventually disappeared; Zone III was the first area to be affected, followed by Zone II, and finally Zone I. Extraction studies with Tween 80 and Tween 60, which extracted the "false" and "true" lipase, resp., showed that these substances are identical in localization, intensity of reaction, granule size (in staining studies), and changes in activity under the influence of ethionine. They were not identical with the carboxylesterase detected by o-acetyl-5-bromoindoxyl.

- 736 THE INFLUENCE OF PROLONGED MORPHINE ADMINISTRATION ON SOME HISTOCHEMICAL REACTIONS IN THE LIVER OF RATS. II. (Pol.) Myca, Z. (1st Clin. Surg., Acad. Med., Zabrze, Poland). Pat. Pol. 17(2):181-190, 1966.

Rats treated with morphine (20 mg/kg/day for 30-120 days s.c.), liver cell RNA increased gradually according to the duration of treatment. Alkaline phosphatase was unchanged after 30 or 60 days; after 90 or 120 days of treatment it was markedly increased in the biliary canaliculi and the areas of the small hepatic arteries. Acid phosphatase activity was increased in the same areas after 30 days of treatment; after 60 days the reaction was more intense and also appeared in the liver cell cytoplasm and in the Kupffer cells; at 90 and 120 days, this reaction was diffuse and intense. A progressive increase in deoxyribonuclease-II activity was also seen; it appeared first in the liver cell cytoplasm (after 30 days of treatment), then spread to the hepatic cell nuclei, then to the Kupffer cells. The clinical implications of prolonged morphine treatment are discussed in the light of these results.

- 737 LIVER INJURY AND THE PREVENTION OF MASSIVE ADRENAL NECROSIS FROM 9,10-DIMETHYL-1,2-BENZANTHRACENE IN RATS. (E.) Wheatley, D. N. (U. Aberdeen, Scotland), I. R. Kernohan and A. R. Currie. Nature (London) 211(5047):387-389, 1966.

Two experiments were performed to evaluate the prevention of massive adrenal necrosis from 9,10-dimethyl-1,2-benzanthracene (DMBA) in rats. In rats pretreated with CCl_4 (0.3 ml of 50% soln. in olive oil i.p.) 24 hr. prior to DMBA admin., CCl_4 protected the adrenal glands from the necrotizing effect of DMBA, but this CCl_4 dose caused centrilobular necrosis of the liver in 85-90% of the rats. Partial hepatectomy 24 hr. before DMBA admin. also afforded adrenal gland protection. DMBA caused massive adrenal necrosis in all rats treated with sham hepatectomy and unilateral nephrectomy. It is concluded that DMBA is itself not adrenocorticolytic, but is metabolized in the liver to a derivative which causes massive adrenal necrosis.

- 738 SUGGESTIVE EVIDENCE OF HEPATOTOXICITY CONCOMITANT WITH THIORIDAZINE HYDROCHLORIDE USE. (E.) Reinhart, M. J. (U. Michigan, Ann Arbor), R. M. Benson, S. K. Kwass and W. F. Storey. J.A.M.A. 197(10):767-769, 1966.

Three cases with suggestive evidence of hepatotoxicity due to the antipsychotic tranquilizer thioridazine HCl (Mellaril) are described. The first patient, with a history of increased serum glutamic-oxalacetic transaminase (SGOT) levels on chlorpromazine, responded to thioridazine with elevated alkaline phosphatase and serum glutamic-pyruvic transaminase (SGPT), as well as clinical jaundice was noted. A patient with a history of parkinsonism and photosensitivity reaction to chlorpromazine presented with a progressive increase in SGPT levels, which continued throughout thioridazine admin. and were accompanied by concurrent pruritus, fatigue, and dark-colored urine. In the third case, the SGPT and alkaline phosphatase values increased during thioridazine treatment. In spite of these findings, treatment with thioridazine was maintained with a resultant return to normal values of SGPT and alkaline phosphatase.

- 11739 OXYPHENYLBUTAZONE AND LIVER REGENERATION. (E.) Bengmark, S. (U. Göteborg, Sweden) and R. Olsson. Acta Chir. Scand. 132(1/2):129-133, 1966.

In partially hepatectomized rats treated with variable doses of oxyphenylbutazone (1.25-10.0 mg/day, parenterally), liver regeneration was higher than in untreated controls, but the differences were not statistically significant. A marked, highly dose-dependent antiphlogistic effect was seen in treated rats; water content was significantly lower in the treated animals than in controls on the second postoperative day, but the water content-reducing effect of the drug was not apparent on postoperative days 4 and 8. No toxic effects of the drug on the liver were observed.

- 11740 INFLUENCE OF ETHANOL ON THE METABOLISM OF PERFUSED NORMAL, FATTY AND CIRRHOTIC RAT LIVERS. (E.) Salaspuro, M. P. (State Alcohol Monopoly Res. Lab., Helsinki, Finland) and P. H. Mäenpää. Biochem. J. 100(3): 768-774, 1966.

In rats fed a low-protein, high-fat diet deficient in lipotropic factors, supplemented by α -tocopherol acetate (5 mg/wk.) and choline (20 mg on days 5 and 11 of the experiment), fatty liver began to develop after about 6 wk. and was well established after 3-4 mo., while cirrhosis developed after 6-8 mo. of this diet. Metabolic studies were performed *in vitro* after addition of ethanol (200 mg/100 ml medium) at various stages of development of liver pathology. Oxygen consumption and CO_2 production were decreased in fatty and cirrhotic livers; ethanol caused almost complete cessation of CO_2 production in normal liver, and a slight decrease in cirrhotic and fatty liver, but had no effect on oxygen consumption in any case. Glucose release was seen in the initial period of incubation in all preparations; it continued normally after addition of ethanol in normal and fatty liver, but the cirrhotic livers showed a marked uptake of glucose, accompanied by release of lactate and pyruvate into the medium. The production of ketone bodies was unchanged from control values in early fatty livers, but decreased in cirrhotic and late fatty livers. The ratio of lactate:pyruvate conc. in the ethanol-containing perfusion medium rose from 11 to 67 in normal liver, from 12 to 16 in early fatty liver, from 13 to 26 in late fatty liver, and from 21 to 55 in cirrhotic liver; the ratio of β -hydroxybutyrate:acetoacetate conc. rose from 1.2 to 8.4; 2.0 to 2.8; 1.2 to 2.4, and 2.1 to 4.0, resp.

- 11741 EFFECT OF ADRENAL HORMONES, METHYLCHOLANTHRENE AND IONIZING IRRADIATION UPON AMINOAZO DYE N-DEMETHYLATING ACTIVITY IN REGENERATING RAT LIVER. (E.) Terayama, H. (U. Tokyo, Japan) and A. Takata. J. Biochem. (Tokyo) 60(1):1-11, 1966.

Whole body irradiation of male Wistar rats with Co^{60} - γ -rays did not affect either the aminoazo dye N-demethylating activity or hydroxylating activity of rat liver, and had no significant effect on induction of enzyme activities by methylcholanthrene (MC); however, irradiation appeared to increase the reduction of enzyme activity after partial hepatectomy. Admin. of cortisone had no significant effect on the N-demethylating action of normal liver but partially prevented the decrease in enzymatic activity caused by epinephrine or partial hepatectomy. Epinephrine caused a large, rapid decrease in N-demethylating activity, which was also observed in MC-treated rats. MC induced N-demethylating activity in partially hepatectomized rats; a large prior dose of MC apparently prevented a decrease in enzymatic activity after partial hepatectomy. After partial hepatectomy or sham operation, N-demethylating activity was reduced greatly (50%) in the liver within a few hr. after operation; in the sham operated group, activity returned to normal within 24 hr. After partial hepatectomy, this activity remained at a low level for 24 hr., then gradually returned to normality over 4 days in parallel with liver regeneration.

- 11742 INCREASE OF ANTIHEMOPHILIC GLOBULIN (FACTOR VIII) IN CASES OF LETHAL NECROSIS OF THE LIVER. (Ger.) Straub, P. W. (U. Zürich, Switzerland), G. Riedler and E. O. Meili. Schweiz. Med. Wschr. 96(37):1199-1204, 1966.

Plasma constituents were determined in 11 patients with severe necrotic liver diseases, such as massive necrotic hepatitis (1 case), acute yellow atrophy of the liver (4 cases), massive fatty degeneration (1 case), fulminating hepatitis

case), acute dystrophy (1 case), and severe cirrhosis (3 cases). All factors involved in blood coagulation were present in plasma in lower than normal conc. in these patients, except Factor VIII which was increased to 1.33 over 10 times normal (av. 4 times highest normal value). In this respect, Factor VIII resembled other plasma globulins, which were also elevated. The serum transaminases were also increased in all patients to about the same degree as the increase of Factor VIII. Diluted plasma from these patients caused normalization of the coagulation time when added to hemophilic blood; no fibrinolysis was observed.

- 743 TRANSITORY HEMOLYTIC ANEMIA IN HYPERLIPEMIA AND LIVER DAMAGE DUE TO ALCOHOLISM. (ZIEVE SYNDROME). (Ger.) Kuhn, D. (U. Heidelberg, Germany), J. Meiser, A. Wagner and G. Neuber. Deutsch. Med. Wschr. 91(37): 1634-1640, 1966.

Three young men (age 27-32 yr.) with Zieve syndrome presented with anorexia, colicky epigastric pain, vomiting, edema, hepatomegaly, low-grade jaundice, hyperlipemia (total lipids 1570-5290 mg%), and hemolytic anemia (hemoglobin 7.8-9.8 g% with an increased number of reticulocytes). The osmotic resistance of the RBC was normal; the RBC half-life was only 12 days (normal over 24 days). An increased activity, not sharply defined, was demonstrable over the spleen. Sternal puncture showed increased erythropoiesis, cells with fatty accumulation, and erythrophagocytosis. With abstinence from alcohol and a protein- and vitamin-rich diet, a uniform recovery from the pathologic changes over 4-6 wk. was seen, without any special therapy. The course of the illness was clarified through continuing clinical, hematological, and biochemical determinations. The pathogenesis of the syndrome is obscure.

- 744 DISTURBANCES IN THE PROTEIN METABOLISM DURING INTOXICATIONS DUE TO TETRACHLORIDE CARBON. PROTECTING ACTION EXERTED BY FOLCYSTEINE-ORERIU. (E.) Oeriu, S. (Chemical-Pharm. Inst., Bucharest, Rumania), D. Winter, S. Sauvard, J. Winter, I. Tanase, N. Carp, V. Cojocaru and E. Vochitu. Rev. Roum. Physiol. 3(2):109-116, 1966.

In rats, folcysteine (0.1 ml/day for 6 wk. s.c.) exerted a protective action against the effects of carbon tetrachloride (CCl_4) intoxication (0.04 ml/day of 10% soln. for 6 wk. s.c.). With respect to elimination of sulfobromophthalein, liver function with CCl_4 and folcysteine was 28% better than in the animals receiving CCl_4 only. The serum albumin and β - and γ -globulin levels tended to be more nearly normal in the presence of folcysteine in animals poisoned with CCl_4 . In animals intoxicated by CCl_4 , serum amino acids (cysteine, histidine, glutamine, glutamic acid, and aspartic acid) were decreased by 32-40%; addition of folcysteine returned these lowered values to within normal limits. RNA values were increased by folcysteine, as was DNA (although to a lesser degree). The histological appearance of the livers intoxicated by CCl_4 in the presence of folcysteine was more nearly normal. Folcysteine treatment did not modify fat accumulation in the poisoned livers; however, with folcysteine the cholesterol content was normal. Lipid metabolism in treated livers poisoned with CCl_4 was very nearly normal. Folcysteine liberates sulfhydryl groups as a consequence of enzymatic transformation of its active principle into formylcysteine.

- 745 SERUM CORTISOL LEVELS IN ALCOHOLIC AND NONALCOHOLIC SUBJECTS DURING EXPERIMENTALLY INDUCED ETHANOL INTOXICATION. (E.) Mendelson, J. H. (Massachusetts Gen. Hosp., Boston) and S. Stein. Psychosom. Med. 28(4): (Pt. 2):616-626, 1966.

Serum cortisol levels increased in both nonalcoholic subjects and alcoholic subjects who were given an 86-proof beverage mixture every 4 hr., day and night for 4 days. The nonalcoholic subjects consumed less alcohol which was partly due to the development of gastrointestinal symptoms characterized by nausea, epigastric pain and vomiting. In these subjects, the rise in serum cortisol levels correlated with the appearance of these gastrointestinal symptoms. Although the alcoholic group did not become ill, their cortisol levels also rose with alcoholic consumption and eventually were higher than the nonalcoholic group, as was the consumption of alcohol. As these subjects showed far more anxiety while drinking, it is felt

that the increased serum cortisol levels in this experiment may correlate more closely with the type of emotional response induced by drinking rather than the amount of alcohol consumed. This concept was further supported by the fact that the highest cortisol levels in the alcoholic group occurred when the subjects were undergoing withdrawal symptoms. The 4 subjects in each of these groups were in good health, had not consumed alcohol for at least 2 mo. and showed no evidence of liver or renal dysfunction.

- 11746 TEMPORARY CONNECTION BETWEEN BLOOD ALCOHOL LEVEL AND CHANGES OF LIPID CONTENT IN BLOOD AND LIVER. (Ger.) Ammon, H. P. T. (U. Erlangen-Nurnberg, Germany), C.-J. Estler, W. Zeller and R. Pfeiffer. Med. Pharmacol. Exp. (Basel) 14(6):585-592, 1966.

Adult male Sprague-Dawley rats received 2.0 mg/g ethanol as a 20% w/v aqueous soln. i.v. over 2 min., then sacrificed by decapitation under ether anesthesia, so that analyses could be performed at 2-hr. intervals after alcohol admin. for 20 hr.; the last two groups were tested at 25 and 30 hr. after inj. Two hr. after inj. the depot fat of the epididymis decreased from 60 mg/g to 450, returning to normal values after 8 hr.; serum free fatty acid increased from 0.7 μ Eq/ml to 1.1, fell after 6 hr. to 0.4, and returned to normal after 14 hr.; fat content of the liver increased from 33 mg/g to 50 in the first 8 hr. and was still somewhat higher than normal after 30 hr.; esterified fatty acids in serum dropped considerably and remained below normal for the duration of the experiments, while serum total cholesterol decreased for the first 8 hr. (from 90 to 60 mg%) and returned to normal after 6 additional hr. The data indicate an intensified fat mobilization in the first 2 hr. after alcohol intake, a continuous rise in the lipid content of the liver, reaching a max. uptake after 8 hr., and a delayed release which was manifest in the persistently low levels (even after 30 hr.) of esterified fatty acids in serum, the higher than initial lipid content of the liver at the end of experiments, and the low serum cholesterol levels seen in the first 10 hr. Since these changes persist for a considerable time longer than the blood alcohol levels (complete elimination in about 4 hr.), short interval alcohol intake in humans has a cumulative effect upon development of alcoholic liver pathology.

- 11747 STUDIES ON THE RELATIONSHIP BETWEEN INCREASED ADENYLIC ACID DEAMINASE ACTIVITY AND CHANGES IN NUCLEAR RNA METABOLISM IN RAT LIVER CAUSED BY THIOACETAMIDE. (E.) Kizer, D. E. (Samuel Roberts Noble Found., Ardmore, Oklahoma), B. A. Howell, J. A. Clouse and B. C. Shirley. Cancer Res. 26(7)(Part 1):1376-1382, 1966.

Female rats (170-200 g) maintained on a standard diet, were admin. multiple, once daily, i.p. inj. of thioacetamide (50 mg/kg body wt.). Control animals received equivalent vol. of 0.9% saline. Some animals received 5-fluorouracil (5-FU) (30 mg/kg body wt.). In most experiments actinomycin D was inj. s.c. once daily for 4 days at 120 μ g/kg body wt. In 1 experiment 1 dose of actinomycin D (650 μ g/kg body wt.) was inj.; in another experiment this dose was divided among 18 inj. admin. at 4-hr. intervals for 72 hr. Orotic acid-6- C^{14} was diluted with saline to give approx. 3.3 μ C/2 ml, inj. i.p. Liver tissue was prepared for microscopic examination specifically for nuclei-nucleoli measurements of diameters. Assays were made for adenosine monophosphate (AMP), inosinic acid extracted and measured, RNA content and isotope content determined. Multiple thioacetamide inj. resulted in 2-3-fold increases in AMP deaminase activity; but simultaneous inj. of actinomycin D or 5-FU with thioacetamide caused no interference with this increase. AMP-deaminase was activated *in vitro* with ATP; however, in the presence of ATP the enzyme activity of thioacetamide-inj. animals was twice that of the saline controls and these increases were not inhibited by 5-FU or actinomycin D. On the other hand, actinomycin D inhibited, but 5-FU enhanced, the increases in diameters of nucleoli caused by thioacetamide inj. Neither 1 nor 4 inj. of actinomycin D alone changed the conc. of nonnuclear nuclear or "nucleolar" RNA and incorporation of orotic acid-6- C^{14} into these fractions was not altered when actinomycin D was inj. simultaneously with thioacetamide; it did not inhibit increases in "nucleolar" RNA content nor increases in the incorporation of orotic acid-6- C^{14} into the nonnuclear nuclear fraction. Single inj. of actinomycin D (650 μ g/kg body wt.), alone or with thioacetamide, inhibited incorporation about 50%. This

high level of actinomycin D was divided into 18 doses and inj. at 4-hr. intervals over a 3-day period to thioacetamide-treated rats. Increases in AMP deaminase activity were not inhibited, but incorporation of labelled orotic acid was inhibited.

11748 THE EFFECT OF ANESTHESIA WITH FLUOTHANE OR ETHYL ETHER ON THE FUNCTION OF THE LIVER CELLS IN OBSTRUCTIVE JAUNDICE. (Pol.) Hryniewiecki, J. (Acad. Med., Poznan, Poland) and L. Wołowicka. Pat. Pol. 17(2):155-162, 1966.

Rats with obstructive jaundice induced by bile duct ligation underwent anesthesia with fluothane (1-2%) or ether of 1-12 hr. duration. Anesthesia was induced again 1 wk. after the first treatment. The existing disturbances of liver cell function were exacerbated by anesthesia; the quantitative changes and changes of distribution of RNA, glycogen, and lipids increased as the duration of anesthesia increased. The RNA and glycogen content decreased and the lipid conc. increased. It is concluded that fluothane or ether anesthesia is contraindicated in liver disease.

11749 THE EFFECT OF METHANDROSTENOLONE ON TISSUE RESPIRATION OF THE LIVER. PROTEIN, FAT AND GLYCOGEN CONTENT IN EXPERIMENTAL CHRONIC TOXIC HEPATITIS. (Rus.) Abdullaev, N. Kh. (Dept. Path., Physiol. Cent. Inst., Improvement Phys., Moscow). Pat. Fiziol. Eksp. Ter. 10(3):36-40, 1966.

Rats with chronic toxic hepatitis induced by CCl_4 (0.12 ml/100 g s.c., 2 inj./wk.) were treated with methandrostenolone (1-2 mg every 2 days p.o.) from the beginning of poisoning (Group 1) or beginning 25 days later (Group 2); the duration of the study was 15-65 days. In Group 1, oxygen absorption and (to a lesser extent) carbon dioxide yield tended to increase during the first 25 days; this activation of respiration became significant at 35-65 days, and was accompanied by a parallel increase in protein and glycogen conc. and a decrease in total lipids. In Group 2, the greatest stimulation of tissue respiration (at 45-65 days) was accompanied by similar changes in protein, glycogen, and total lipid.

11750 EXPERIMENTAL STUDIES ON THE EFFECT OF ADENOSINE TRIPHOSPHATE ON TOXIC LIVER DAMAGE. (Ger.) Pelz, L. (U. Rostock, Germany) and D. Tessmann. Zschr. Ges. Exp. Med. 140(4):368-376, 1966.

In male and female Wistar rats, p.o. admin. of carbon tetrachloride (0.05 or 0.15 ml/100 g body wt.), was followed after an interval of 30 min. to 30 hr. by i.p. or i.p. plus s.c. admin. of ATP, 28-84 mg of the Na-salt. The extent of toxic liver damage was determined on the basis of serum glutamic-pyruvic transaminase (SGPT) levels and pathomorphological findings. A sex-related reaction pattern was observed: male rats showed a significantly greater increase in SGPT activity than females following CCl_4 admin., and also significantly lower levels than the controls following ATP admin.; in female rats, the difference between treated and control animals was not statistically significant. In all instances, the degree of histomorphological liver damage corresponded closely to the changes in SGPT activity.

11751 HEPATOTOXICITY AFTER METHOXYFLURANE ADMINISTRATION. (E.) Klein, N. C. (New York Hosp.-Cornell Med. Ctr., N. Y.) and G. H. Jeffries. J.A.M.A. 197(12):1037-1039, 1966.

The case history of what is believed to be the first nonfatal case of suspected methoxyflurane (Penthrane) hepatotoxicity with documented hepatocellular necrosis is presented. Thiopental-methoxyflurane anesthesia was admin. to a 58-yr.-old Negro woman in order to perform a local radium implant into a vaginal tumor. Other than the vaginal lesion, the patient was in excellent condition: there was no blood loss or circulatory changes during the procedure. Although the liver margin was palpable 2 cm beneath the right costal margin on admission, liver function tests were normal. However, within 2 days after the methoxyflurane admin. the patient complained of fatigue. By postoperative day 10, the urine had darkened, the stools had lightened and jaundice was evident. At this time the liver was palpable 8 cm beneath the costal margin, the liver function tests were markedly abnormal and eosinophils were 28%. Eight days later the symptoms had abated and liver function tests began to show a trend toward normal. During this time, diphenoxylate hydrochloride with atropine, tetracycline, prochlorperazine and prednisolone had been admin. A percutaneous liver biopsy 4 wk. after the onset of the symptoms was

characterized by centrilobular necrosis with reticulin collapse; a second biopsy 3 wk. later showed regeneration and restoration of liver structure. Evidence from the previous other 2 fatal case reports plus that obtained experimentally indicates that this damage is a hypersensitivity-type reaction rather than true hepatotoxicity

- 11752 PORPHYRIA INDUCED IN RATS BY OROTIC ACID AND THE EFFECT OF ADENINE-5'-MONOPHOSPHORIC ACID. (E.) Gajdos, A. (Hotel-Dieu, Paris, France), M. Gajdos-Torok, A. Palma-Carlos and L. Palma-Carlos. Nature (London) 211(5052):974-975, 1966.

Rats were fed diets containing 1% orotic acid for 1-3 wk., and adenosine triphosphate (ATP), adenosine-5'-monophosphate (AMP), total liver lipids, ether-soluble porphyrins (copro- and protoporphyrin), γ -aminolevulinic acid (ALA), and ALA synthetase in the RBC, liver, bone marrow, and feces were measured. Liver ATP was significantly reduced in rats fed orotic acid (from 164.5 to 60 μ moles/100 g net wt.) to 164.5 for the controls for 1-3 wk. Total lipids increased from 8.4 to 38 g/100 g net wt.; and there was no change in RBC ATP conc. Urinary porphyrin excretion remained constant over 3 wk. of orotic acid feeding, but fecal and RBC porphyrin levels increased. After 2 wk. of orotic acid feeding, liver mitochondrial ALA synthetase increased from 4.5 to 19.8 μ moles ALA formed/mg protein. Admin. of AMP (20 mg/rat i.m.) reduced the excess porphyrin levels in liver (from 16.2 to 11.6 μ g/100 ml net wt.) and RBC (from 69 to 43 μ g/100 ml) and ALA synthetase activity in liver mitochondria (from 35 to 19.8 μ moles ALA/mg protein). A reduction in the synthesis of ATP is probably related to porphyria. These results provide some evidence that the enhancement of porphyrin biosynthesis by orotic acid is related to a decrease in the formation of ATP by the liver.

- 11753 EXPERIMENTAL PORPHYRIA INDUCED IN RATS BY ETHIONINE. (E.) Palma-Carlos, A. (Hotel-Dieu, Paris, France), L. Palma-Carlos, M. Gajdos-Torok and A. Gajdos. Nature (London) 211(5052):977-978, 1966.

Three groups of rats were treated with ethionine (0.5% in diet, 50 mg/day for 1 wk. p.o., or 100 mg/day for 2 days p.o., resp.); the first 2 groups received a low-protein diet (8% casein for 3 wk. or 12% casein for 1 wk., resp.), and the third group received a normal diet. Urinary and fecal γ -aminolevulinic acid (ALA) and coproporphyrins increased in ethionine-treated rats of all groups, especially Groups 1 and 2. The levels of ether-soluble porphyrins (copro- and protoporphyrins) in the liver increased significantly in Groups 2 and 3, but not in Group 1; liver porphyrin conc. increased from 11.0 to 17.1 μ g/g liver in Group 2, and from 8.4 to 13.6 μ g/g liver in Group 3. Porphyrin levels in RBC increased significantly in Groups 1 and 2 (41.0 to 116.5 and 33.0 to 62.0 μ g/100 ml, resp.); they were not measured in Group 3. Ethionine feeding for 3 wk., 7 days, or 2 days caused an accumulation of porphyrins in the urine, feces, liver, and RBC with a corresponding decrease in the liver adenosine triphosphate (ATP) levels. These results agree with earlier work by the authors on the effects of 6-mercaptopurine and orotic acid, which suggest that the experimental inhibition of ATP biosynthesis is accompanied by porphyria.

- 11754 SOME CLINICAL EFFECTS OF GUANOXAN. (E.) Frohlick, E. D. (Cleveland Clin., Ohio), H. P. Dustan and I. H. Page. Clin. Pharmacol. Ther. 7(5):599-602, 1966.

Guanoxan, an adrenergic neuron-blocking agent (2-guanidine-methyl-[1,4]-benzodioxan sulfate) was tested in 10 patients as an antihypertensive drug for periods from 2-62 wk. (av. 22 wk.) at daily dosages of 20-200 mg (av. 72 mg). Good control of supine arterial pressure was achieved in 5 patients only; disturbing postural dizziness was reported by 6 patients. All patients demonstrated an attenuated or abolished Valsalva overshoot response. Incapacitating diarrhea was reported in 5 patients. No abnormalities of renal function were noted. Of special importance was the development of abnormal hepatic function in 3 patients; in 2 instances increased serum glutamic-oxalacetic transaminase activity was the only evidence; in the third patient, this was associated with elevation of alkaline phosphatase, and sulfo-bromophthalein retention. Liver function returned to normal 2-3 wk. after cessation of guanoxan treatment.

- 755 STUDIES ON EXPERIMENTAL LIVER FIBROSIS OF RATS SENSITIZED WITH EGG ALBUMIN. (Jap.) Monna, T. (Osaka City U. Sch. Med., Japan). Osaka Shiritsu Daigaku Igakubu Zasshi (J. Osaka City Med. Ctr.) 14(7-9):343-355, 1965.
- Histological changes of the liver were followed in rats treated with 1% egg albumin i.v., 3 inj./wk. for 5-14 wk.); changes in the serum proteins, portal pressure, and spleen were also examined. In Group 1, only albumin was admin. In Group 2, bilateral ligation of the renal pedicles was carried out 1 wk. before the start of sensitization. In Group 3, renal pedicle ligation was followed by admin. of streptokinase (1000 U/100 g s.c.) on the same day as albumin admin. In Group 4, prednisolone (0.2 mg/100 g i.m.) was admin. after renal pedicle ligation (as in Group 3). The intensity of liver fibrosis was not always correlated with the period of sensitization; the progress of fibrosis was almost similar among the first groups. Fibrous tissue initially formed a central septum intermingled with a peripheral septum; the lobules were finally divided into small islets of parenchymal cells by the fibrous tissue. These animals also showed marked splenomegaly, portal hypertension, an increase of tissue plasminogen activator in the liver, and hyper-globulinemia. The most marked proliferation of the fibrous tissue in the liver was found in Group 3. Prednisolone treatment (Group 4) had a significant inhibitory effect on the progress of fibrosis.
- 756 OXYGEN CONSUMPTION BY BRAIN TISSUE AND FREE NUCLEOTIDE CONTENT OF THE BRAIN DURING LIVER FUNCTION DISTURBANCE IN RATS. (Uk.) Kurskii, M. D. (Inst. Biochem., Ukrainian Acad. Sci., Kiev, USSR) and O. N. Zriakov. Ukr. Biokhim. Zhur. 38(3):269-273, 1966.
- In rats poisoned with CCl_4 (0.15 ml/100 g liver wt. i.p.), the brain tissue showed an increase in creatinine phosphate without a significant change in total nucleotides or inorganic phosphate 12 hr. later. At 24 hr. all the above components except adenosine triphosphate increased; after 48 hr. the guanosine triphosphate and inorganic phosphate decreased. Oxygen consumption of the cerebral tissue mitochondria increased, with an increase of the respiratory control index (indicating intensification of oxidative phosphorylation) 24 hr. after CCl_4 admin. Partial hepatectomy caused a decrease in oxygen consumption and the respiratory control index, but had no significant effect on the nucleotide, nucleotide phosphate, creatinine phosphate, or inorganic phosphate levels after 24 hr. Possible mechanisms of the effect of CCl_4 and partial hepatectomy on brain tissue metabolism are discussed.
- 757 ACUTE LIVER INJURY IN DUCKLINGS AND RATS AS A RESULT OF OCHRATOXIN POISONING. (E.) Theron, J. J. (Nat. Nutr. Res. Inst., Pretoria, South Africa), K. J. van Der Merwe, N. Liebenberg, H. J. B. Joubert and W. Nel. J. Path. Bact. 91(2):521-529, 1966.
- Ducklings (30 days old) and weanling rats, in groups of 30 each, were given by stomach tube 100 μg of crystalline ochratoxin A (an isolated aflatoxin from Aspergillus ochraceus) and killed at varying times up to 24 hr. after treatment. A portion of the liver was removed for histochemical and ultrastructural investigation. An increase in fatty vacuolation was noted in duck liver, and periodic acid-Schiff stain showed damage to the mitochondria. No histochemical changes in alkaline phosphatase, acid phosphatase, ATPase, inosine diphosphatase (IDPase) and thiamine pyrophosphatase (TPPase) were noted. The electron microscope studies showed rounded, swollen mitochondria with a coarsely granular matrix and compressed cristae. Morphological changes in the endoplasmic reticulum were found at an early stage with reduction in Golgi lamellae and ribosomal granules. Rats given ochratoxin A developed liver cell necrosis 8-24 hr. after treatment. The activity of IDPase was found in cells associated with centrilobular regions, but no other change in any of the enzymes studied was noted. The rat liver, under electron microscopic examination, showed marked changes in endoplasmic reticulum involving marked hypertrophy of the smooth and agranular endoplasmic reticulum with formation of compact masses of smooth membranes. This hypertrophy corresponded to the hyaline cytoplasmic degeneration noted with the light microscope.

- 11758 EXPERIMENTAL STUDIES ON THE METABOLISM OF ALDOSTERONE. II. STUDIES ON THE METABOLISM OF ALDOSTERONE IN CCl_4 -TREATED DOGS. DOGS WITH INTERCEPTION OF HEPATIC CIRCULATION AND DOGS WITH LIGATION OF THE RENAL ARTERY AND VEIN. (Jap.) Moriya, K. (Fac. Med., Kyoto U., Japan). Naika Hokan (Jap. Arch. Intern. Med.) 13(2):79-93, 1966.

The metabolism of tracer doses of 7- H^3 -D-aldosterone ($20 \mu\text{c}/\mu\text{g}$) or 1,2- H^3 -D-aldosterone ($100 \mu\text{c}/\mu\text{g}$; each a single i.v. dose) was studied in dogs. In dogs with liver damage induced by CCl_4 (0.5-1.0 ml/kg), metabolism and metabolic clearance of aldosterone was reduced; urinary aldosterone metabolites in the 1-hr. urine fell, and the liver:plasma ratio of aldosterone metabolites also decreased. Disturbances in the enzymatic system regulating aldosterone metabolism in the liver were suggested, but there were no marked changes in the levels of aldosterone metabolites in the plasma of CCl_4 -treated dogs. Parenchymal damage was seen in the kidneys, which may have delayed urinary excretion of aldosterone metabolites. In dogs with interruption of liver circulation (portacaval shunt with ligation of the gastroduodenal, right gastric, and common hepatic arteries), the aldosterone disappearance curves were almost flat, showing that the liver is the primary metabolic site. Renal aldosterone metabolism was suggested by a relative increase of the 3-oxo conjugate in the urine. A significant decrease in aldosterone metabolism and clearance was also seen in dogs with ligation of the renal artery and vein. It is concluded that aldosterone is metabolized in both the liver and (to a lesser extent) the kidneys.

- 11759 HISTOLOGICAL CHANGES OF THE RABBITS' LIVER WITH THE LAPSE OF TIME AFTER THE INTRAVENOUS INJECTION OF THOROTRAST. (Jap.) Kaneda, H. (Kyoto Pref. U. Med., Japan) and T. Kobayashi. Nippon Igaku Hoshasen Gakkai Zasshi (Nippon Acta Radiol.) 25(10):1238-1241, 1966.

A Thorotrast soln. (2 ml/kg) was admin. i.v. in 3 equal doses on 3 consecutive days to rabbits. Radiological and histological examination of the liver was performed from 1 day-27 mo. later. At 1 hr. after Thorotrast admin., X-ray examination revealed homogeneously scattered shadows in the liver and spleen; the liver shadows became progressively nonhomogeneous and reticular. At 1-2 mo. after admin., Thorotrast was deposited in the Kupffer cells and liver cells; Kupffer cells were rounded and swollen, but no injuries to liver parenchyma were noted. At 3 mo., Thorotrast granules deposited in the Kupffer cells were gathered together in the sinusoid and moved to Glisson's capsule; the liver connective tissue increased, and liver cells became atrophied. With continued passage of time, a large amount of atrophy in the liver cells and a marked liver fibrosis occurred. At 26 mo. pronounced atrophy of the liver cells, proliferation of the connective tissue, and scattered nodular proliferation of the liver cells were seen; 1 specimen showed numerous clumps of proliferative bile ducts in the liver.

- 11760 COMPLETE SEVERANCE OF THE COMMON HEPATIC DUCT DUE TO EXTERNAL BLUNT TRAUMA. (E.) Scheinin, T. M. (Cent. U. Hosp., Turku, Finland) and E. S. Heikkinen. Acta Chir. Scand. 131(6):516-519, 1966.

Viral Hepatitis

- 11780 OVERPRODUCTION OF DEOXYRIBONUCLEIC ACID AS A CAUSE OF CELL DEATH IN CULTURES INFECTED WITH CANINE HEPATITIS VIRUS. (E.) Moulton, J. E. (U. California, Davis), L. M. Frazier and S. P. Garg. Am. J. Vet. Res. 27(119):1128-1130, 1966.

After 36 hr. incubation, electron microscopy showed cytopathic changes in approx. 25% of a secondary culture of canine kidney cells cultivated in vitro and infected with canine hepatitis virus. When 5-fluorodeoxyuridine was added to the culture after 12 hr. incubation, 87% cell survivals were found at the end of the total incubation period, versus 47% in controls. In the treated culture, total virus production was 92% of that seen in the control culture, a difference which was shown to be statistically nonsignificant. It is concluded that cell deaths were primarily associated with uncontrolled over-production of viral DNA, due to interference with intracellular biosynthetic regulatory mechanisms, rather than with the synthesis of complete, infective viruses as much; the mechanism of action involved probably entailed depletion of substances normally used for the synthesis of cellular DNA and other compounds which are essential to cell viability.

- 11781 SERUM ENZYMIC ACTIVITY DURING THE EVOLUTION OF ACUTE VIRUS HEPATITIS. ACTIVITY OF ENZYMES WHICH ARE CONFINED, WITHIN THE CELL, TO THE MITOCHONDRIA AND THOSE WHICH ARE CONFINED TO THE SOLUBLE FRACTION OF THE CYTOPLASM. (It.) Giglio, F. (U Hosp., Palermo, Italy), A. Notarbartolo, S. Le Moli, P. Citarella and L. Pagliaro. Boll. Soc. Ital. Biol. Sper. 42(7):331-334, 1966.

During the evolution of 68 cases of acute virus hepatitis, tabulations were made of the mean serum levels of 3 enzymes whose intracellular site is the mitochondria (glutamic dehydrogenase, ornithine carbamyl transferase and the cationic fraction of glutamic-oxaloacetic transaminase) and of 4 whose intracellular site is the soluble fraction of the cytoplasm (the anionic fraction of glutamic-oxaloacetic transaminase, sorbitol dehydrogenase, phosphohexose isomerase and glutamic-pyruvic transaminase). During the initial stages of infection, total serum enzymatic activity in the first group, above, was increased by approx. 1700%; that in the second group, by approx. 9600%. Glutamic dehydrogenase activity showed a gradual, progressive decline after the middle of the second wk., while the other 6 enzymes began to behave in the same way by the middle of the first wk. The initial increase in the serum enzymatic activity of the "mitochondrial" enzymes appeared to follow that of the "cytoplasmic" enzymes, suggesting that the initial cellular damage was contained within the cytoplasm, with subsequent extension to involve the mitochondria. There was no indication as to whether such a sequence, if it was actually present, represented an effect directly attributable to the virus or one which resulted from the intervention of a secondary, nonspecific, intracellular mechanism of defense.

- 11782 EFFICACY OF TREATMENT WITH GAMMA GLOBULIN IN YOUNG CHILDREN INFECTED WITH VIRAL HEPATITIS. (It.) Rasi, F. (Prov. Inst. Child Welfare, Padua, Italy). Minerva Pediat. 18(7):347-349, 1966.

Following exposure to viral hepatitis, 32 of 60 institutionalized children, 1-5-yr. old, showed significantly increased levels of serum glutamic-oxaloacetic and/or serum glutamic-pyruvic transaminase, with inversion of the normal ratio of these 2 substances. This combination was constructed as positive evidence of active infection. In an additional 14 of 60, both levels were extremely high, without inversion of the normal ratio, suggesting that they were either carriers of infection or unusually highly susceptible. Within 2 wk. after inj. of 4 ml (0.23-0.32 ml/kg) γ -globulin, transaminase levels and ratio were normalized in 23 of 32 children in the first group; the ratio alone had been normalized in an additional 4 of 32; 5 of 32 showed no significant change but were normalized following inj. 2 or 3 (2 ml/dose). Transaminase levels were normalized in all 14 in the second group, following a first inj. as above. An additional 14 of 60, in whom initial levels were within normal range and the ratio was normal, received a 2-ml prophylactic inj. as soon as the exposure was discovered. None of the children in any group developed clinically active hepatitis.

- 1783 EXPERIMENTAL STUDIES ON HEPATITIS EPIDEMICA. III. MORPHOLOGIC LESIONS IN THE SPLEEN AND LYMPH NODES OF MICE INFECTED WITH THE MOTOL VIRUS. (E.) Kowalczykova, J. (Med. Acad., Cracow, Poland), K. Szczidrawa, A. Laskowski and M. Zembala. Acta Med. Pol. 7(2):191-198, 1966.
- The morphologic characteristics of the lesions produced by the Motol virus are described. Seventy inbred mice were inj. i.p. with 1.1 ml viral suspension in phase 2 (100 LD₅₀). This normally elicits typical hepatitis which is lethal when infection occurs in early spring or autumn and winter. Histologic examination of the spleens and abdominal lymph nodes was made and the types of changes and the dynamics of their development are discussed. On the second day after infection, 5 of 5 mice showed hyperemia and slight proliferation of lymphatic and reticulo-endothelial cells of the spleen. On day 3 lymph follicle necrosis and edema of the spleen red pulp arose. Necrosis began at the periphery of the lymph follicles, and in advanced necrosis edematous walls and narrowed lumen characterized the central arterioles. This necrosis was accompanied by megakaryocyte disappearance. From days 3-17 various necrotic lesions of different intensity appeared in all mice, while the retroperitoneal lymph nodes were enlarged and exhibited small necrotic foci in the most serious cases. Regression of pathologic symptoms occurred in 2 cases and spleens were normal.
- 1784 HISTOCHEMICAL AND FUNCTIONAL STUDIES CONCERNING THE ETIOLOGY OF HYPER-SIDEREMIA IN ACUTE VIRAL HEPATITIS. (It.) Scuro, L. A. (U. Padua, Italy), G. Dobrilla, A. Innecco, A. Lechi, G. Monti and L. Okolicsanyi. Polio-clinico [Med.] 73(2):73-82, 1966.
- Routine laboratory tests of 29 patients were conducted between days 7 and 14 of hospitalization. Blood samples taken at hours 1, 3, 6, 10 and 16 after admin. of 1 g desferrioxamine metasulfate was followed by plotting of sideremic curves to determine the degree of ferrochelation. Siderinurea was measured by a modified Scuro method. Perls' method for ferric iron was used with liver specimens. Rack's test for sideremia and Ventura's test of unsaturated iron-binding capacity were also employed. A high degree of siderosis was seen in all patients, although only 2 different liver sections showed positive histochemical reactions for iron. Heavily necrotic liver cells, surrounded by inflammatory material, were common. Desferrioxamine admin. resulted in ferrochelation of circulating ferritinic iron, decreased sideremia (18.1%) but increased siderinurea, the latter reaching transient pathologic levels in a majority of cases. It was concluded that acute hepatocytic necrosis during the infection may result in increased levels of blood ferritin which, as these results indicate, may give rise to siderosis. The use of the sideremic curve and the desferrioxamine test may be valuable tools in obtaining information about the genesis of hepatic necroses.
- 1785 THE EFFECT OF METHANDROSTENOLONE ON GLYCOGEN CONTENT IN THE LIVER AND ON SOME PATHOCHEMICAL SHIFTS IN FAT METABOLISM IN EXPERIMENTAL CHRONIC TOXIC HEPATITIS. (Rus.) Abdullaev, N. Kh. (Dept. Path. Physiol., Cent. Inst. Improv. Phys., Moscow). Probl. Endokr. Gormonoter. 12(4):106-109, 1966.
- Male albino rats with chronic toxic hepatitis (CTH) induced by carbon tetrachloride (0.12 ml/100 g s.c.) received methandrostenolone (1-2 mg/100 g every 2 days, p.o.) immediately after poisoning (Group I) or beginning 25 days after CCl₄ (Group II). In Group I, inhibition of liver fat accumulation was seen only near the end of treatment (day 55-65) and was accompanied by an increase in glycogen and an activation of autolipolysis (from day 45). The lipolytic activity of fatty tissue was basically unchanged (only on day 45 and 55 was it increased). Serum levels of free high molecular wt. fatty acids remained basically unchanged (decreased on day 35, increased on day 65), while the level of β -lipoproteins was increased on days 35 and 65, but remained unchanged during other periods. In Group II during simultaneous admin. of CCl₄ + methandrostenolone, liver glycogen increased, the fat content decreased, lipolytic activity in liver was stimulated (during 20-30 days of combined treatment), and serum β -lipoproteins were increased. Changes of lipolytic activity of fatty tissue and serum levels of free high molecular wt. fatty acids were regular.

LIVER AND BILIARY TRACT

Viral Hepatitis

- 11786 INDUCTOTHERMY APPLICATION IN THE COMPLEX THERAPY OF CHILDREN WITH EPIDEMIC HEPATITIS. (Rus.) Nadtochii, A. S. (Cent. Sci. Res. Inst. Health Resort Sci. Physiother., Min. Health, USSR). Vop. Okhr. Materin. Dets. 11(4): 17-21, 1966.

The effects of conventional therapy (rest, diet, polyvitamins, glucose and corticosteroids in severe disease) were enhanced by inductothermy (10 min./day; 10-15 procedures/course) in 80 children (age 3-15 yr.) with mild (51), moderately severe (26) or severe (3) epidemic hepatitis of 14-20 days duration. In the treated cases hepatomegaly was present at the time of discharge in only 1 case of mild hepatitis and 4 with moderately severe disease. In 80 other children (same age range) with mild (59) or moderately severe (21) hepatitis not treated by inductothermy, hepatomegaly persisted in 33 cases of mild disease and 16 cases of moderately severe disease. Total serum bilirubin levels in treated patients with mild disease decreased from 3.2 to 0.62 mg% in the first 5 wk. of therapy (compared to 3.25-0.98 mg% in controls); in patients with moderately severe disease, total serum bilirubin fell from 6.0 to 0.8 mg% in the first 6 wk. of treatment (6.2-1.2 mg% in controls). The thymol turbidity test and serum proteins were normalized more quickly in treated cases. This treatment was well tolerated. One case history is given.

- 11787 DISTURBANCE OF COBALT METABOLISM IN PATIENTS WITH CHRONIC HEPATITIS AND THE USE OF THIS MICROELEMENT FOR TREATMENT. (Rus.) Ol'gina, F. P. (Med. Inst., Ivano-Frankovsk, USSR). Klin. Med. (Moskva) 44(5):132-134, 1966.

A group of 24 patients with chronic hepatitis received complex therapy including cobaltous chloride (3 x 20 drops/day of 2% soln. for 20 days p.o.); 12 control patients received complex therapy without cobalt. Before treatment, the cobalt content (in $\mu\text{g}\%$ in ashes) in the blood, urine and feces of treated patients was 80-480 (av. 237), 40-340 (av. 176), and 140-540 (av. 367), resp., compared to normal values of 468, 120, and 132, resp. In the 12 controls, these values were 120-320 (av. 241.6), 100-260 (av. 160.8) and 180-440 (av. 316.6), resp. In cobalt-treated patients, these values after treatment were 125-2040 (av. 817), 340-4460 (av. 1130) and 700-5100 (av. 1754), resp.; compared to 140-340 (av. 227), 60-260 (av. 153.6), and 150-440 (av. 347), resp., in control cases. Cobalt therapy resulted in improvement of the general condition, decrease or disappearance of pain in the liver region, improvement in appetite, and decreased hepatosplenomegaly. Improvement was less marked in the controls.

- 11788 SOME CLINICAL AND BIOCHEMICAL INDICES IN PATIENTS WITH INFECTIOUS HEPATITIS DURING HORMONAL TREATMENT. (Rus.) Staroselskii, D. V. (Dept. Infect. Dis., Crimea Med. Inst., USSR). Vrach. Delo (4):108-110, 1966.

In 9 of 26 patients with infectious hepatitis treated with prednisolone (30-40 mg/day for 10 days; dosage reduced toward the end of the course) the blood bile acid content was markedly increased during the first few days of treatment, but at the end of treatment it was similar to that of the 13 untreated control patients (av. 5.1 and 6.6 mg%, resp.). Serum cholesterol was about the same in treated and control patients (increase to 260 mg% at the end of treatment, compared to 216 mg%). Bilirubin levels were parallel to cholesterol levels. After 3 days of treatment with ACTH (20-40 U/day for 7 days), a brief increase in serum bile acids occurred in 1 of 4 cases; 2 patients showed a rapid decrease, and no changes occurred in the other patient. Cholesterol changes were irregular during ACTH therapy. Before the treatment, the av. cholesterol content was 185 mg% and the av. bile acid content was 14.0 mg%; in 20 healthy persons the av. cholesterol conc. was 155 mg%, while bile acids were absent from the serum. During hormonal therapy, bilirubinemia was reduced in 29 of 30 treated patients. The time of hospitalization was not reduced by prednisolone therapy (av. 42.8 days; controls 41.8 days).

- 11789 ABO-BLOOD GROUP DISTRIBUTION IN INFECTIOUS HEPATITIS. (Ger.) Thieler, H. (Med. Acad. Erfurt, Germany), H. Schmechel and F. Gaerisch. Zschr. Inn. Med. 21(12):365-368, 1966.

VER AND BILIARY TRACT

Viral Hepatitis

patient population of 1,039 subjects, composed of 314 cases of acute infectious hepatitis and the rest with past histories of infectious hepatitis, was tested for the distribution frequency of major blood groups (as well as D/d) and compared with results obtained from analysis of a normal population of 100,000 subjects. The frequency of A, B, O, and AB groups in patients and normal subjects were 43.41% and 44.03%; 13.57% and 13.64%; 37.54 and 36.69%; and 5.49 and 5.64%, resp. The frequencies for Groups D and d were 81.13% and 80.72%, and 18.87% and 19.28%, resp. None of the differences are statistically significant.

- 1790 INTENSIVE CORTICOTHERAPY OF SHORT DURATION IN EPIDEMIC HEPATITIS. (Rum.) Căruntu, F. D. (Commun. Dis. Hosp., Bucharest, Rumania). Med. Intern. (Bucur.) 18(8):965-972, 1966.

Three groups of patients with epidemic hepatitis of about the same stage and intensity were treated with conservative maintenance therapy (33; Group 1), with prednisone in a prolonged course (40-50 mg/day for 11-28 days; gradually reduced to an av. of 24 mg/day; av. total 360 mg over 14.3 days) (32 patients; Group 2), or with brief courses of prednisone as above (av. 40.5 mg/day; av. total 210 mg over 5.4 days; in 21 cases concluded with ACTH, 50 U/day for av. 3.5 days) (27 patients; Group 3). Jaundice responded favorably in 21 of 32 cases in Group 2; good general condition and appetite were restored in 27. The overall clinical picture was good in 19, satisfactory in 9, and unimproved in 4. Four relapses occurred; steroid therapy was resumed in 2 cases. In Group 3, jaundice improved in 24 of 27 cases; subjective improvement and improved appetite were seen in 25. Clinical results were good in 19, av. in 7, and none in 1 case. Three relapses occurred; corticosteroid therapy was resumed in 2 cases. Serum bilirubin levels were normalized (to under 1.5 mg%) in 27 of 31 patients in Group 2 and 20 of 26 patients in Group 3; serum glutamic-oxalacetic transaminase levels fell below 100 in 10 and 11, resp. (they were originally elevated in 26 patients in each group); thymol turbidity tests were normalized in only 6 of 31 and 5 of 27 cases, resp. Criteria measured were normal in 20 of 26; 11 of 26; and 5 of 27. Av. duration of disease was 51 days in Group 1, 52 days in Group 2, and 50 days in Group 3; the av. duration of icterus was 33.5, 44, and 41.3 days, resp.; the av. duration of hospitalization was 36.3, 41, and 39.1 days, resp. It is suggested that short and intensive corticosteroid therapy is less disadvantageous and should be considered superior to the longer therapy in cases where dyspeptic disturbances, general debility, or prolonged jaundice are present.

- 1791 DIPYRRROMETHENURIA IN ACUTE HEPATITIS. (Ger.) Netoušek, M. (Motol Hosp., Prague, Czech.) and M. Moravec. Med. Klin. 61(36):1421-1422, 1966.

Using a quantitative spectrophotometric method, an accurate determination of 2 urinary fractions of dipyrromethene was done on 66 patients, 64 of whom underwent rigorous tests of liver function; 30 patients had mild acute hepatitis, 12 had severe acute hepatitis, and 24 had cholangiohepatitis. The 2 fractions were the native mesobilifuchsin (also termed native fuchsin) and the leukobase which polymerizes into fuchsin; these two fractions were described as total fuchsin (total urinary fuchsin, although dipyrromethene is also excreted in the bile). The av. values for urinary native and total fuchsin excretion were: mild acute hepatitis 31 and 38 mg/day, resp; severe acute hepatitis 82 and 108 mg/day, resp.; and cholangiohepatitis 55 and 68 mg/day, resp. The biochemical pathway in the formation of dipyrromethene is unknown; the amount of dipyrromethene increases in diseases of the liver, while fecal excretion is also increased, so that increased urinary fuchsin excretion does not simply reflect a change in the excretory route.

- 1792 EFFICACY OF GAMMA GLOBULIN PROPHYLAXIS AGAINST INFECTIOUS HEPATITIS IN ESTABLISHMENTS FOR CHILDREN. (Ger.) Eichhorn, D. (Dresden-Neustadt Hosp., Germany) and H.-J. Dietzsch. Deutsch. Gesundh. 21(36):1599-1604, 1966.

LIVER AND BILIARY TRACT

Viral Hepatitis

Serum glutamic-pyruvic transaminase levels and thymol turbidity were examined in 819 children and 102 adults exposed to infectious hepatitis, before and after prophylactic treatment (0.02 ml/kg) with γ -globulin, to detect cases of subclinical hepatitis before prophylactic treatment and to uncover failures of the prophylaxis. No cases of icteric hepatitis occurred after admin. of γ -globulin. These individuals were grouped according to the results of the laboratory tests and physical findings (such as palpable hepatomegaly). At the time of γ -globulin treatment, previously unrecognized hepatic disease was diagnosed in 35 children (latent hepatitis in 15, anicteric hepatitis in 20). The incidence of these subclinical diseases was particularly high among children in nurseries; the incidence declined steadily with age. The γ -globulin prophylaxis failed in 1.7% of the group (14 children and 1 adult); the hepatitis was latent in 9 and anicteric in 5. A higher incidence of prophylactic failure occurred among the younger children. It is important to discover these subclinically infected individuals in order to provide adequate treatment and to eliminate them as carriers of infection. Because of the high rate of failure (1.7%) of the prophylaxis, doubling of the dose of γ -globulin is recommended (0.04 mg/kg).

- 11793 ABNORMAL BEHAVIOR OF SERUM GLUTAMIC-PYRUVIC TRANSAMINASE IN THE ACUTE STAGE OF VIRAL HEPATITIS. (Ger.) Hofmann, H. (United Health Installations Hosp., Leipzig, Germany). *Zschr. Ges. Inn. Med.* 21(13): 391-395, 1966.

In 89 of 536 patients with acute viral hepatitis, serum glutamic-pyruvic transaminase curves examined over a period of 11-14 wk. showed an atypical behavior. Two principle patterns were observed: in 1, the usual decline during the first 3 wk. after the appearance of jaundice was followed by a new rise during wk. 4 to 5. In the second, the declining curve took a protracted course. With increasing age of the patient, these atypical patterns were associated increasingly with subicteric relapses or a protracted decline of the bilirubin levels; in older patients (av. age 57 yr.), the secondary rise in serum glutamic-pyruvic transaminase activity was sometimes followed by a severe clinical relapse with jaundice.

- 11794 ASPECTS OF OVARY FUNCTION IN CHRONIC POST-VIRAL HEPATITIS. (E.) Stan, M. (Inst. Intern. Med., Bucharest, Rumania), M. Popa, A. Pappo, C. Miron and V. Runcan. *Rev. Roum. Med. Int.* 3(3):197-208, 1966.

Of 47 female patients with chronic post-viral hepatitis (mean age of 35.4 yr.), 83% complained of premenstrual disturbances. This was a higher percentage than in the control group (women of the same age with other internal disease), as was the percentage of acidophilic cells in the cytovaginal smears in the luteal phase indicating a defect in luteinization. The mean estrogen excretion both in the folliculin and luteal phase was normal in both groups, but when only the cases having severe cirrhotic hepatitis with splenomegaly or with evolutive cirrhosis are considered, the estrogen excretion was significantly greater. No correlation could be established between estrogen excretion and gamma globulin percentage or serum aldolase activity, however, except in cases of cirrhosis with hypohormonal amenorrhea, a good correlation between estrogen excretion and sulfobromophthalein retention was found in the hepatitis patients. The rate of hypohormonal amenorrhea was significantly higher in this group than in the control group, particularly with advanced evolutive cases. This was probably due to an unspecific hypophyseal inhibition through protein deficiency and malnutrition. Also, the number of cases of amenorrhea with normal estrogen excretion was greater in the hepatitis group.

- 11795 INVESTIGATIONS OF THE LACTACIDEMIA AND PYRUVICEMIA DURING MUSCULAR STRESS IN PATIENTS WITH CHRONIC POST-VIRAL HEPATITIS. (E.) Pappo, A. (Inst. Intern. Med., Bucharest, Rumania), I. Apostolescu, M. Georgescu, R. Cretescu, M. A. Zamfirescu-Gheorghiu and V. Runcan. *Rev. Roum. Med. Int.* 3(2):99-108, 1966.

A total of 71 subjects, 53 of whom had chronic post-viral hepatitis, compensated portal post-hepatitis cirrhosis, or chronic hepatitis, were divided into 2 groups. Group 1 consisted of 12 normal subjects and 31 hepatitis patients who underwent

termination of lactic and citric acid levels in venous blood after a 30-min. light exercise period. Group 2 consisted of 6 controls and 22 hepatitis patients who were stressed for 15 min., followed 30 min. later by measurement of blood lactic, citric, and pyruvic acids. In Group 2 the levels of lactic and citric acids were 13.12 and 5.17 mg%, resp., for hepatitis patients before stress, compared to 24.47 and 6.4 mg%, resp., after stress. In the normal subjects the citrate levels rose 2.6 mg% in stress and the lactate levels increased 9.93 mg%. In subjects undergoing moderate muscular stress, the pyruvate and lactate levels increased 0.16 and 1.0 mg%, resp., in hepatitis patients, and decreased 0.08% and 2% resp., in normal subjects. Both hepatitis patients and normal subjects showed a decrease in blood lactate towards pre-stress levels after 60 min. of rest after stress. Any attempt to use blood lactate or pyruvate levels as a measure of quick fatigue (especially in hepatitis patients) would seem successful only in cases of extreme fatigue. Lactacidemia variations as a function of stress were more marked in chronic post-viral hepatitis cases than in hepatitis cases of other origins. Patients with chronic hepatitis showed increased base values of pyruvic acid in the venous blood; citric acid levels were less increased in the hepatitis patients than in healthy subjects after muscular stress.

796 HEPATITIS COMPLICATING CHRONIC HAEMODIALYSIS. * (E.) Friedman, E. A. (Kings County Med. Ctr., Brooklyn, N. Y.) and G. E. Thomson. Lancet 2(7465):675-678, 1966.

Among 19 patients treated with a total of 1407 hemodialyses because of intrinsic renal disease, 6 contracted hepatitis with 2 deaths and 4 recoveries. The 19 patients were transfused with a total of 1119 U of whole blood or packed RBC; the subjects who contracted hepatitis received 395 U altogether ranging from a minimum of 19 U in 1 case to 208 in another. Considering the total number of transfusions admin. to all 19 patients, the infectivity rate was 0.5%. In terms of the number of U received by the 6 patients who contracted hepatitis, the infectivity rate of blood was 1.5%. No more than 1 case occurred at any 1 time. Secondary cases occurred among staff members or in the families of patients or staff, leading to the inference that these cases were serum hepatitis rather than infectious hepatitis. Previous subclinical infection and transient passive immunity conferred by the γ -globulin present in the multiple transfusions may explain the relatively low attack rate.

797 FOLLOW-UP STUDY OF CASES FROM THE DELHI EPIDEMIC OF INFECTIOUS HEPATITIS OF 1955-1956. (E.) Chuttani, H. K. (Maulana Azad Med. Coll., New Delhi, India), A. S. Sidhu, K. L. Wigs, D. N. Gupta and V. Ramalingaswami. Brit. Med. J. 2(5515):676-679, 1966.

Outbreak of infectious hepatitis occurred in the city of New Delhi in 1955-56. This paper deals with a follow-up study of 304 persons who had acute hepatitis during the epidemic and of 1,070 persons who were their family contacts. The follow-up took place 5 yr. after the epidemic. The study consisted of clinical assessment in all patients and of biochemical and liver biopsy studies in a proportion of them. Biochemical studies included the determination of total serum protein, serum albumin and globulin, thymol turbidity, alkaline phosphatase, bilirubin, and sulfobromophthalein excretion. Except for an enlarged palpable liver in 4.9% and non-specific digestive symptoms in 18.4% of the epidemic cases, no clinical evidence of liver damage was observed. There were no cases of cirrhosis or scarring of the liver among the 65 liver biopsies. In 109 of 114 individuals studied biochemically there was no abnormality uncovered indicating hepatic damage. In the 5 cases with minor biochemical deviations from the normal, the liver biopsies were normal.

798 COURSE OF THE RESTORATIVE PERIOD AFTER INFECTIOUS HEPATITIS (BOTKIN'S DISEASE). (Rus.) Afinian, V. M. (Ivanovskii Inst. Virol., Acad. Med. Sci. USSR, Moscow). Sovet. Med. 29(6):103-107, 1966.

656 patients convalescent from epidemic hepatitis of slight (61.1%), moderately severe (36.3%), or severe extent (2.6%), symptoms seen within 6 wk. after release included dyspepsia (32.1%), astheno-vegetative symptoms (21.4%), hepatomegaly (21.4%),

LIVER AND BILIARY TRACT

Viral Hepatitis

and splenomegaly in 5.4%. Biochemical indices were not normalized. Within the first 6 wk., complete cures (absence of subjective and objective symptoms and normal laboratory findings) were obtained in 58.2%; the posthepatic syndrome was present in 26.8%, and chronic hepatitis in 1.7%; similar values after 6 mo. and 1 yr. were 60% and 64.6%; 23.4% and 18.5%, and 3.3% and 3.6%, resp. Disappearance of the convalescent-symptoms was associated with normalization of liver size. In the patients without or with accompanying and preceding diseases, complete cures were seen within the first 6 wk. in 75.2% and 42.3%, resp., after 6 mo. in 73.7% and 53.4%, resp., and after 1 yr. in 75.6% and 57.2%, resp. Complete cures after 1 yr. were obtained in 75.3% of the patients with mild disease, in 53.4% of the patients with moderately severe disease, and in 33.4% of patients with severe disease. Liver biopsy in 24 convalescents showed that a morphological cure was not parallel with a clinical cure. Liver biopsy in 3 patients with clinical, biochemical and morphological signs of chronic hepatitis verified the diagnosis. Chronic hepatitis was excluded by biopsy in 14 patients with clinical changes and normal liver morphology and laboratory findings, but the posthepatic syndrome developed in 12 cases and after-symptoms in 1; in 7 patients with clinical and morphological abnormalities and normal biochemical findings, chronic hepatitis was also excluded by biopsy. The diagnostic utility of liver biopsy in convalescents is discussed.

- 11799 SIGNIFICANCE OF THE HETEROHEMAGGLUTINATION REACTION WITH COCK ERYTHROCYTES FOR DIAGNOSIS OF ANICTERIC FORMS OF EPIDEMIC HEPATITIS. (Rus.) Koshil, O. I. (S. M. Kirov Milit. Med. Acad., Leningrad) and E. A. Nemirovskaya. *Zhur. Mikrobiol.* 43(6):36-40, 1966.

A positive heterohemagglutinin reaction with chicken RBC (at a titer of 1:10 or over) was seen in 4 puppies with toxic hepatitis induced by CCl_4 (40% soln. s.c.), but this reaction was negative in 4 normal puppies. The hemagglutinin reaction was also positive in 8 of 100 healthy subjects. In 109 patients with anicteric infectious hepatitis of 1, 2, 3, or 4 wk. duration, this reaction was positive in 82%, 58%, 29%, and 20.5%, resp. Similar values in 151 patients with icteric infectious hepatitis were 92%, 68%, 50%, and 30%, resp. Serum aldolase and transaminase activities were increased in all cases of icteric infectious hepatitis in the first 7 days of the disease, and in 89-96% of cases of anicteric hepatitis. The heterohemagglutinin reaction was positive in 8% of 394 control subjects, including blood donors and patients with pulmonary tuberculosis as well as patients with obstructive jaundice and exacerbated chronic cholangiohepatitis. Positive reactions were also seen in 22 of 948 patients with histories of exposure to the anicteric hepatitis, 8 patients with hepatitis in the pre-icteric phase, and 19 patients with chronic cholangiohepatitis. It is concluded that this heterohemagglutinin test, while not of differential diagnostic value, can be used as a screening test.

- 11800 PROLONGED JAUNDICE IN THE COURSE OF VIRAL HEPATITIS. (Pol.) Pruszyński, R. (Dept. Intern. Med., Gdansk, Poland). *Pol. Arch. Med. Wewn.* 36(5):657-662, 1966.

In 1000 patients with viral hepatitis seen in 1955-1960, prolonged jaundice (for 6 wk. or more) was seen in 169 cases. The incidence of prolonged jaundice increased with age, being 2 of 8 in infants under 12 mo., 4.8% (20 of 420) at age 1-15 yr., 18% (58 of 323) at age 16-30, 29.6% (45 of 152) at age 31-45, and 45.4% (44 of 97) at age 46-70 yr. In 78 of these patients, jaundice lasted longer than 2 mo. (over 4 mo. in some cases). The incidence of prolonged jaundice was 10.3% (72 of 332) in epidemic hepatitis, 46.5% (54 of 102) in serum hepatitis, and 23.5% (43 of 138) in hepatitis of doubtful origin.

Cirrhosis

- 11817 ANEMIA AND POLYCYTHEMIA IN LIVER CIRRHOSIS. (Ger.) Hadnagy, C., Z. Bras L. Kelemen and E. Szentkiralyi. Deutsch. Zschr. Verdaul. Stoffwechselkr. 26(1):14-20, 1966.

A study of 213 patients with cirrhosis showed that 80.5% of the 123 males and 63.6% of the 77 females were anemic to varying degrees. The 13 patients not included in the above percentage had secondary anemias due to bleeding. Four of the patients had autoimmune acquired hemolytic anemias (etiology of cirrhoses: posthepatic, idiopathic, malarial, and syphilitic). A parallel study of 50 patients with acquired hemolytic anemia revealed 4 cirrhotics. Of 15 bone marrows studied, sideroblastosis was found in 2; 3 of 213 had polycythemia (Mosse-syndrome). A detailed discussion of data and findings from the literature is given. It is concluded that etiology of the anemia in cirrhotic patients is a complex combination of hypervolemia, increased hemolysis, decreased RBC lifespan and decreased erythropoiesis. Bleeding, or bleeding tendency in some cases and the possibility of impaired liver erythropoietin function(s) are also to be considered.

- 11818 INCREASED IRON-59 ABSORPTION IN PATIENTS WITH HEPATIC CIRRHOSIS. (E.) Friedman, B. I. (U. Kentucky Med. Ctr., Lexington), J. W. Schaefer and L. Schiff. J. Nucl. Med. 7(8):594-602, 1966.

Absorption of Fe⁵⁹-ferrous citrate from the gastrointestinal tract was studied using Bonnet's method in 8 normals and 22 patients with hepatic disease. All but 1 were biopsied. Normally 1 μ c Fe⁵⁹ citrate, 350 μ g ferrous ammonium sulfate and 300-700 of ascorbic acid were admin. p.o. All subjects fasted 12 hr. before test. Stools were collected for 7 days, dried, homogenized and aliquots counted in a well-type scintillation counter, and compared to standard dilutions of the test soln. Av. Fe⁵⁹ absorption in normals was 50.4%, compared to 74% for the patients. In the patient group there was no difference in absorption in the presence or absence of portosystemic shunt. The effect on iron absorption depended on the presence of liver disease alone. No correlation was found with anemia, serum iron, unsaturated iron binding capacity, bone marrow iron, or liver function tests. A low correlation was found with α_2 -globulin.

- 11819 STUDY OF EXCHANGEABLE Na AND K AND OF THE EXTRA-CELLULAR FLUIDS IN ALCOHOLIC CIRRHOSIS. (Fr.) Roberti, A. (Cent. Hosp., Argenteuil, Val-d'Oise, France), H. Traverso, P. Vesin, R. Viguie and P. Blanchon. Sem. Hop. Paris 42(28):1714-1718, 1966.

Eleven anascitic cirrhotic patients (8 males, 3 females) and 20 ascitic cirrhotic patients (15 males, 5 females) were tested for exchangeable sodium (NaE) by Na²⁴, exchangeable potassium (KE) by K⁴² and for extracellular fluids (ECF) by Br⁸². Twelve were retested after treatment. Blood electrolyte sample tests were taken biweekly and urinary Na and K tests taken each day. Blood circulating levels of Na and K did not parallel NaE and KE levels. NaE and ECF values were parallel and increased in cirrhotics with ascites. NaE values were 53.8 mEq/kg in one sick patient and 43 in the normal, while extracellular liquids (ECL) were 37% of the wt. during cirrhosis and 29 normally. Treatment lowered both these levels, although some may be due to loss of body wt. In cirrhosis without ascites NaE was increased significantly about 22% of normal values. This was accompanied by a 25% ECL increase which indicated an infraclinical retention of salt and water. In simple cirrhosis KE varied within normal limits between 7 and 9% while 32% lower levels appeared in cirrhosis with ascites. This low level was around 1.900 mEq/kg and below, and was constantly decreasing, making it a valuable prognostic aid. Anascitic cirrhosis was characterized by a normal or subnormal KE and variations in NaE and ECL showing the existence of infraclinical edema. Corticosteroid treatment tended to reestablish homeostasis and did not deplete K ions as other authors have maintained.

- 11820 BEHAVIOR AND REGULATION OF SERUM NONESTERIFIED FATTY ACIDS (NEFA) AND GLYCEMIA IN HEPATIC CIRRHOSIS. (It.) Crepaldi, G. (U. Padua, Italy), A. Tiengo, G. Enzi and P. Avogaro. Fegato 12(1):21-34, 1966.

When pretreatment serum conc. of non-esterified fatty acids were assayed in 24

ients suffering from hepatic cirrhosis, values obtained for the patients were ce those of normal controls (947 ± 227 versus 418 ± 168 $\mu\text{Eq/liter}$). When the rhotic patients were given norepinephrine ($150 \mu\text{g/kg}$) or glucagon ($16 \mu\text{g/kg}$), re was also a reduced hyperglycemic response. Glucose tolerance tests (250 g cose, p.o.) showed that cirrhotic liver patients had a 'plateau' curve with ayed return to normal. This oral glucose tolerance test also reduced plasma c. of non-esterified fatty acids by 80% in the patients, but by only 60% in mal controls. Norepinephrine evoked the customary response in normal subjects, reasing serum conc. of these compounds by 110%. However, patients with cirrhotic ers showed only a 38% increase. It is suggested that the inability of cirrhotic ients to respond to norepinephrine is due to the inability of adipose tissue, ch is already over-stimulated in these patients, to respond to the additional mulation provided by the hormone.

- 21 LATE RESULTS OF SPLENECTOMY IN HEPATIC CIRRHOSIS. (Rus.) Apakova, S. A. (Sanit.-Hyg. Inst. Med., Leningrad, USSR). Vestn. Khir. Grekov. 96(5): 31-35, 1966.

enectomy alone (16 cases) or in combination with other surgeries (100 cases) ulted in a total survival of 85 of 116 patients with liver cirrhosis. Of 82 ivors observed for 1-9 yr., 12 died within the first yr. and 9 at different es after surgery. Late results showed that 33 of 40 patients with surgery in decompensation stage and 17 of 22 patients with surgery in the stage of sub- ensation were alive; also 15 of 17 patients with hemorrhage and 19 of 23 pa- nts with ascites were alive. Following splenectomy alone none of 13 survivors d during the observation period; the portal pressure decrease was not persistent er splenectomy alone. Only 1 of 14 survivors with splenectomy and vascular stomosis died 4 yr. after surgery; portal hypertension decrease persisted, but effect on the course of the cirrhosis was not always favorable. Of 45 sur- rs with splenectomy and organ anastomosis (omentopexy) 10 died at different es after surgery (1-5 yrs. after surgery in 8 of 10); this surgery could be d in the combat of portal hypertension, showed a specially favorable effect in case of ascites and prolonged life in most of the patients. One of 10 sur- rs with splenectomy and hepatic artery ligation died 2 yr. after surgery; te results were the same as without ligation of the hepatic artery, however, out omentopexy ascites did not disappear in all the cases. The only survivor n splenectomy and ligation of the left gastric artery felt weak and had pain in right hypochondrium, but there were no hemorrhages.

- 22 THE INFLUENCE OF PARTIAL HEPATECTOMY IN EXPERIMENTAL NUTRITIONAL CIRRHOSIS IN THE RAT... (E.) Bengmark, S. (U. Göteborg, Sweden), R. Olsson and B. Rehnström. Acta. Chir. Scand. 132(1/2):112-128, 1966.
- ver cirrhosis was induced in male rats by feeding a choline-deficient diet for o.; partial hepatectomy was then performed in 50% of the animals (the others rving as controls), and both groups were sacrificed 5.5 mo. later. Histological mination of the operated animals revealed thinning and elongation of fibrous beculae, which suggested a stretching of the trabeculae caused by proliferation the parenchymal cells enclosed by the fibers. The amount of fibrous tissue was luced due to partial hepatectomy, but this was not always confirmed by hydroxy- line determinations. Nucleic acid determinations indicated a more normal liver operated animals, which was consistent with the histological findings. Func- onal capacity of the liver, as determined by examination of serum protein frac- ns at sacrifice, was not affected by partial hepatectomy.

- 3 DECOMPENSATED CRYPTOGENIC AND ALCOHOLIC CIRRHOSIS IN SINGAPORE. A CLINICAL STUDY OF 100 PATIENTS. (E.) Seah, C. S. (Thomson Road Hosp., Singapore) and C. H. Tay. Singapore Med. J. 6(4):207-212, 1966.
- management of 100 patients with decompensated liver cirrhosis (40 with histo- ical confirmation) during a 4-yr. period (1961-end of 1964) is described. In s group, there were 73 Chinese, 20 Indians, and 7 Malays (85 men, 15 women). were from poor social circumstances, and 53 (including 2 women) were chronic

LIVER AND BILIARY TRACT

Cirrhosis

alcoholics. Initial clinical features of liver failure were edema in 70%, jaundice in 61%, and ascites in over 59%. Upper gastrointestinal hemorrhage occurred more frequently in patients with alcoholic (20 of 53 or 37%) than cryptogenic cirrhosis (6 of 47 or 12%); ascites occurred more frequently in cryptogenic (64%) than in alcoholic cirrhosis (49%); 33 of the 52 alcoholics had hepatic coma. There were 42 deaths after an av. survival of about 8 mo., 22 in the alcoholic group; hepatic coma preceded death in 20 of the 42 patients. Various associated disorders encountered in this study are also described (malignancy, diabetes mellitus, haemochromatosis, duodenal ulcer, renal disease, congestive heart failure, and active pulmonary tuberculosis). Treatment consisted of diet, usually with vitamin supplements; 13 patients received prednisolone, 11 were treated with testosterone, and 17 with refractory disease received aldactone. The relative effects of various treatment regimes could not be evaluated, but 22 of the 44 survivors were alive after more than 1 yr., and 6 had been followed for 4 yr. (14 were lost to follow-up).

- 11824 THE HEMODYNAMICS OF PORTO-SYSTEMIC CHANNELS AS STUDIED BY RADIOACTIVE TRACERS IN NORMAL AND CIRRHOTIC PATIENTS. (E.) Dal Palu, C. (U. Padua, Italy), G. Donaggio, G. Roberti, I. Dal Zotto and M. Matteucci. Acta Isotop. (Padova) 5(3):271-288, 1965.

A method for the study of porto-systemic hemodynamics in normal subjects and in cirrhotic patients with and without portosystemic shunts is presented. The procedure was carried out in fasting subjects in the supine position; a needle for splenoportography is introduced into the spleen under radioscopic control. With the needle properly located 1-2 ml of human serum ^{131} -albumin is introduced after positioning of scintillation detectors, the first over the hepatic area over the eighth intercostal space on the mid-axillary line, and the second at the fourth intercostal space near the left border of the sternum, the precordial position. The arrival and conc. of the tracer are recorded simultaneously by dual tracings on the same chart. Splenoportographs were obtained for all subjects. In normal subjects the hepatic curve showed a quick rise to a peak (within 5 seconds) of radioactivity; the precordial curve had a somewhat slower onset (peak delayed until 20-25 seconds after inj.). Cirrhotic subjects with no shunts showed a slow rise in the precordial curves with lower conc. for both precordial and liver curves indicating a slower than normal rate of circulation. Cirrhotic patients with porto-systemic shunts showed a more rapid onset and greater conc. of radiation in the precordial curves than on the liver tracings. This was dependent on the amount of shunting and the type and degree of cirrhosis.

- 11825 LIVER CIRRHOSIS AND DIABETES MELLITUS. STUDY OF 140 COMBINED CASES. (Ger.) Müting, D. (U. Med. Clin., Homburg/Saar, Germany), N. Lackas, H. Reikowski and S. Richmond. Deutsch. Med. Wschr. 91(33):1433-1438, 1966. From 1958-1965, the incidence seen at the authors' clinic of combined cases of liver cirrhosis and diabetes mellitus increased 7-fold, compared to increases of 2-fold in cirrhosis and 3-fold in diabetes. In 103 of 140 patients liver cirrhosis occurred first; the developing diabetes was slight, but became more severe as the hepatic insufficiency increased. The reasons for the increase in liver diabetes are to be found in the improved functional diagnosis of all disturbances of blood sugar regulation in cases of liver disease.

- 11826 THE HEMODYNAMICS OF THE HEART IN LIVER CIRRHOSIS. SYNOPSIS [OF THE PROBLEM] AND STUDY OF 50 PATIENTS IN REGARD TO THE ELECTROCARDIOGRAM AND ROENTGENOGRAM. (Ger.) Schmidt, J. (U. Erlangen-Nürnberg, Germany) and H. Gusinde. Zschr. Kreislaufforsch. 55(3):312-328, 1966.

Changes in cardiac hemodynamics as a result of liver cirrhosis occur in about 1 of 2 patients. The pathogenetic mechanisms are discussed extensively on the basis of clinical and experimental literature data. Porto-pulmonary anastomoses and shunts as a result of portal hypertension, arterio-venous pulmonary and bronchopulmonary anastomoses as a result of general vasodilatation, and an increase in circulating blood volume are the underlying causes of increased cardiac output which, in turn, leads to hypertrophy of the heart, particularly of the left ventricle. Analysis of

the histories, X-rays and electrocardiograms of 50 patients with liver cirrhosis (10 male, 12 female, av. age 59.3 yr.) showed clear-cut evidence of left ventricular hypertrophy in 8 cases where primary cardiovascular disturbances had been excluded; 6 additional patients had less pronounced symptoms. While none of these patients died of cardiac failure, the extraportal hemodynamics of patients with liver cirrhosis seem to warrant special consideration.

27 LACK OF ASSOCIATION BETWEEN CIRRHOSIS AND THE COMMON TYPES OF COLOR BLINDNESS. (E.) Fialkow, P. J. (U. Washington Sch. Med., Seattle), H. C. Thuline and L. F. Fenster. *New Eng. J. Med.* 275(11):584-587, 1966. In 46 alcoholic patients with Laennec's cirrhosis were studied for color-vision defects (using the Hardy-Rand-Rittler protocol), 11 of 24 males and 9 of 22 females were initially scored as having color-vision defects. One of these was recorded as having a rare blue-yellow defect (tritanopia) and 19 were recorded as having a red-green defect. However, when 9 of these patients were tested during convalescence, 7 were recorded as normal. Furthermore, when 31 inpatients were tested for a red-green defect, 18 were recorded as positive, whereas, when the test was done on 15 outpatients, only 1 was recorded as having a defect. This would indicate that the vision defects found in association with liver cirrhosis (and alcoholism) are secondary to the disease rather than a genetic one. These data, plus the fact that many women presented positive results in this study, dispute the contention that people with X-linked genes for defective color vision are predisposed to alcoholism or liver cirrhosis. In this study, the results found by the tests of the Hardy-Rand-Rittler and those found by the more specific Ishihara test did not correlate well.

28 THE COMPARATIVE EFFECT OF CHLOROTHIAZIDE AND MERALLURIDE ON THE DEVELOPMENT OF HEPATIC ENCEPHALOPATHY IN CIRRHOTIC PATIENTS. (E.) Weisberg, H. (N. Y. Med. Coll., New York), R. J. Strobos, W. S. Rosenthal, H. D. Appleton and G. B. J. Glass. *Gastroenterologia (Basel)* 105(6):321-334, 1966. Hepatic encephalopathy occurred far more frequently following the admin. of chlorothiazide than following meralluride treatment when each was given in full therapeutic doses (1.5 g/day in 3 doses and 2 ml. i.m., resp.) for a 10-day period to the same cirrhotic patient. With the chlorothiazide, 7 of 11 patients (including 4 with portacaval shunts) developed encephalopathy with characteristic electroencephalographic abnormalities. With the meralluride therapy, only 1 shunted patient developed encephalopathy, although abnormal electroencephalographic changes were seen in the other 2 shunted patients despite the absence of any neuropsychiatric symptoms. The development of neuropsychiatric abnormalities was associated with hyperammonemia, an increase in plasma bicarbonate, hypopotassemia, extensive fluid loss and the presence of marked portal systemic collateral circulation. While meralluride produced encephalopathy less often than chlorothiazide, it was no less effective as a diuretic agent causing an av. wt. loss of 1 ± 5 pounds. Chlorothiazide admin. resulted in an av. wt. loss of 8 ± 6 pounds.

29 SPUR-SHAPED ERYTHROCYTES IN LAENNEC'S CIRRHOSIS. (E.) Siiber, R. (New York U. Sch. Med., N. Y.), E. Amorosi, J. Lowe and H. J. Kayden. *New Eng. J. Med.* 257(12):639-642, 1966. A second case of "spur-cell anemia" is presented which clinically resembles the first reported case except that the RBC morphology, i.e. spur-shaped RBC, was not corrected by normal plasma or serum, nor was the serum or plasma able to induce spur formation in normal erythrocytes in vitro. Also in this case, unlike the first case, the red-cell cholesterol levels remained within the normal range which tends to refute any etiologic role by cholesterol in this RBC abnormality. The similarities of this case history, a 45-yr.-old woman, to the initial one included a history of high alcoholic intake, hepatosplenomegaly and severe hemolytic anemia which did not respond to the admin. of adrenocorticosteroid hormones (prednisone, 20 mg/day). Furthermore, thrombocytopenia was found in both patients and Laennec's cirrhosis was tomically diagnosed in both. In vitro, the abnormal autohemolysis was correctable with ATP, but not with glucose, normal plasma or vitamin E. No abnormalities of hemolytic enzymes, lipids or electrolyte transport were detected in the RBC of

LIVER AND BILIARY TRACT

Cirrhosis

this patient. A splenectomy was performed when this patient failed to respond to prednisone, but the postoperative course was complicated by massive i.p. bleeding (requiring the admin. of 39 blood units) and the patient died. Portal cirrhosis was confirmed at autopsy. Whether "spur-cell anemia" represents a new entity or whether it is only a variant of severe liver disease still remains to be seen.

- 11830 ALTERED CLEARANCE OF FREE AMINO ACIDS FROM PLASMA OF PATIENTS WITH CIRRHOSIS OF THE LIVER. (E.) Iob, V. (U. Michigan Med. Sch., Ann Arbor) W. W. Coon and M. Sloan. J. Surg. Res. (Boston) 6(6):233-239, 1966.

Eight volunteer normal subjects and 8 cirrhotic patients received a test meal of protein prior to which fasting blood samples had been taken; 5 hourly samples of blood were taken after the meal. The test meal was hydrolyzed and analyzed for amino acid content. The plasma of the fasting sample and the pooled plasma of the 5 hourly blood samples for each individual were also analyzed for amino acid content after removal of protein. The quantitative analysis of the different amino acids was done by the automated column chromatographic technic except for tryptophan which was determined by a spectrofluorometric method. Eight volunteers and 8 cirrhotic patients received an i.v. infusion of essential amino acids; a blood sample was taken prior to infusion and then at 1/2, 1, 2, 3, 4, and 5 hr. after completion of the infusion. Each sample was separately analyzed quantitatively for amino acids. Urine samples were collected during the 5-hr. test and the amino acid content determined. There was no significant difference between controls and cirrhotics in urinary amino acids. The results of the protein test meal show that the disappearance of the branched-chain amino acids (isoleucine, leucine, and valine) is more rapid in cirrhotics than in normal subjects. Although lysine, methionine and threonine seem to have a more rapid clearance their rates are not significant. Three cirrhotic patients tested 3-9 mo. after portacaval shunt showed substantially the same values as in the original test. Results of the i.v. infusion of amino acids showed increased significant clearance of the same amino acids as in the protein meal test. In addition the clearance of threonine after infusion increased and became significant, whereas the clearance of tryptophan decreased.

- 11831 LIPID NATURE OF CEROID IN EXPERIMENTAL NUTRITIONAL CIRRHOSIS. (E.) Norkin, S. A. (Womans Medical College, Philadelphia, Pa.). Arch. Path. (Chicago) 82(3):259-266, 1966.

Rats were fed a low-protein, cirrhosis-producing diet with tocopherol-stripped corn oil (22% of diet) for up to 35 wk. The liver lipids extractable by chloroform:methanol were separated on silicic acid columns and the triglycerides analyzed by gas chromatography. The precipitate formed after chloroform-methanol extraction was re-extracted in a Soxhlet-acetone, then saponified in 10% KOH (which liberated 1-2% of dry, defatted liver wt. in the first 9 wks.); the resulting brown soln. was extracted with ether. Increasing amounts of ceroid (acid-fast copper colored pigments) appeared in the livers of choline-deficient rats, reaching a max. of 20% of the dry defatted wt. by wk. 35. Concomitant histochemical analysis showed ceroid in the liver residue up to the point of KOH hydrolysis. The linoleic and arachidonic acid levels were low, compared to triglycerides, in the hydrolyzate, which contained a predominance of saturated fatty acids of the C16 and C18 group. The proportions of the extractable fatty acids and the lipid portion of the ceroid were dependent on the fatty acid composition of the dietary oil. The tocopherol-free diets caused a shift in the composition of the triglyceride mixture, causing a loss of 27% of the linoleic acid in the first 24 hr. and 53% in 48 hr. It is suggested that liver triglycerides are the precursors of ceroid in experimental nutritional cirrhosis, and that certain of the unsaturated fatty acid analogs are lost through oxidative polymerization.

- 11832 CONTRIBUTION TO THE STUDY OF THE HEMODYNAMICS OF HEPATIC CIRRHOSES. (Fr.) Blanchon, P. (Cochin Hosp., Paris), C. Raynaud, R. Georges, J. Gontier, A. Roberti, H. Traverso, P. Vesin and R. Viguié. Sem. Hop. Paris 42(28): 1699-1707, 1966.

LIVER AND BILIARY TRACT

Cirrhosis

even patients with anascitic cirrhosis of the liver and 20 with ascitic cirrhosis (10 of 20 studied before and after regression of ascites) received human serum albumin labeled with ^{131}I , 15 mc in 0.5 ml soln., i.v., in a study of total cardiac output, rate of systolic flow, variations of total blood vol. and effectiveness of renal irrigation. In both groups, the mean cardiac output was approx. normal but ranged from approx. 3.25-approx. 8.9 liters/min., as against a normal range of 4.25-5.0. Output was above normal range in 9 of 31, below normal range in 9 of 31. The mean systolic flow among anascitic patients was 76.7 ml/systole, as against 64 ml/systole among ascitic patients, with the number of systoles/min. ranging from 60-85 and from 80-110, resp. In both groups, the ratio of cardiac output to total circulating blood vol. was elevated by approx. 20%, except for 7 of 20 ascitic patients, in whom it was reduced by 10-30%, apparently due to impairment of ventricular function. In anascitic patients, effective renal irrigation was essentially normal; in ascitic patients, it was almost decreased significantly, with a very marked decrease of the renal fraction in the cardiac output. In 6 of 10 patients in whom ascites regressed, a significant increase of cardiac output followed regression, accompanied by a parallel increase of systolic flow and of the ratio of cardiac output to total circulating blood vol. Two patients in whom regression was spontaneous showed increases of 20% and 69%, resp., in the rate of effective renal irrigation; 4 in whom it was induced by corticotherapy showed increases of 1.8%, 37%, 42% and 105%, resp.; 4 in whom it was induced by a diuretic, furosemide, showed reductions of 4%, 16%, 37% and 52%, resp., accompanied by an increase of cardiac output and total circulating blood vol. The decrease of effective renal blood flow in response to a diuretic was ascribed to an increase of renal vascular resistance.

1833

EXPERIENCE WITH THE MODERN CLASSIFICATION OF LIVER CIRRHOSES. (Rus.)

Mansurov, Kh. Kh. (Tadzhik Inst. Gastroenterol., Acad. Med. Sci. USSR, Stalinabad). Klin. Med. (Moskva) 44(6):46-53, 1966.

Examination of 214 liver biopsies from 132 patients with cirrhosis showed postnecrotic cirrhosis in 122 biopsies (57%), septal cirrhosis in 33 specimens (15.4%), biliary cirrhosis in 8 specimens (3.7%), and cirrhosis of undetermined type in 51 specimens (23.9%). Postnecrotic cirrhosis was characterized by irregularly developed fibrosis, large bands of connective tissue, regenerative foci of various sizes with pronounced polymorphism of epithelial cells of different sizes, distinct proliferation of reticular cells with focal accumulation at the site of focal necrosis, and irregular glycogen distribution in the parenchyma. Septal or portal cirrhosis differed from the postnecrotic type by a peculiar development of the connective tissue starting from the central veins and portal tracts or formed within the parenchymal lobes. The liver cells were also often decreased in size and had light cytoplasm; binucleated cells were usually found on the periphery of nodes of regeneration, the connective tissue had many vessels and lymphatic fissures, and the parenchyma showed focal proliferation of fibroblastic elements and reticular cells. Biliary cirrhosis specimens showed marked biliary stasis, sometimes combined with cholangitis and cholangiolitis, marked connective tissue proliferation with a less pronounced formation of regeneration nodes, fibrosis of the portal tracts with proliferation of biliary ducts, and large biliary thrombi in the parenchyma. An attempt was made to differentiate these types of cirrhosis by clinical and laboratory findings. Laboratory data were not suitable as a differential diagnostic method, but demonstrated well the clinical activity of the disease. It is concluded that liver biopsy is a necessary adjunct to clinical and laboratory data for the differential diagnosis of the various morphological types of liver cirrhosis.

1834

HEMOCHROMATOSIS AND HEMOSIDEROSIS: ESPECIALLY THEIR RELATION TO THE

LIVER CIRRHOSIS. (Jap.) Yamaguchi, H. (Fac. Med., U. Tokyo, Japan) and M. Nomura. Nippon Ketsueki Gakkai Zasshi (Acta Haemat. Jap.) 28(7):905-913, 1966.

Biopsy (283) and autopsy (103) specimens of the liver or liver plus pancreas were examined for hemosiderin deposits, which were graded 0 to 3+ in intensity. Hemosiderin deposits were found more frequently in specimens from patients with cirrhosis than in those from patients with diseases not involving the liver. In the

LIVER AND BILIARY TRACT

Cirrhosis

cirrhotic specimens the distribution of hemosiderin was parenchymal for the most part; in patients with blood diseases treated with multiple blood transfusions, the pigment was located primarily in the Kupffer cells. None of the patients with leukemia, aplastic anemia, or other blood diseases had cirrhosis. There was no significant correlation between the amount of hemosiderin deposition and age, sex, family and clinical histories, physical findings, and most laboratory data in patients with cirrhosis, except that pancreatic fibrosis and hemosiderosis, abnormal serum iron values, and hemosiderin deposition in the Kupffer cells were more frequently noted in cirrhosis patients with 2+ and 3+ hemosiderin deposits. Characteristic symptoms of hemochromatosis (hepatomegaly, diabetes mellitus, and skin pigmentation) were noted in patients with cirrhosis with or without hemosiderin deposits in the liver; marked (3+) hemosiderin deposition in the liver parenchymal cells was found in alcoholic and nonalcoholic cirrhosis in almost equal frequency. Iron absorption (determined by a double-isotope method) was under 10% in 5 normal subjects, but over 10% in 10 of 15 cirrhosis patients; there was no significant correlation between iron absorption and liver hemosiderin, although increased iron absorption may be an etiologic factor for excess iron deposition in liver cells. There were many intermediate stages between simple liver cirrhosis and classical hemochromatosis with respect to iron deposition and other factors.

- 11836 SOME INDICES OF THE BLOOD COAGULATION SYSTEM IN HEPATIC CIRRHOSIS BEFORE AND AFTER OPERATION. (Rus.) Tadzhiyev, K. T. (Tadzhik Med. Inst., USSR) and C. I. Rakhimov. Klin. Khir. (Kiev) (5):15-17, 1966.

Gallbladder and Biliary Tract Diseases

- 837 HEPATIC ARTERIAL INTERRUPTION IN THE FETUS---AN ATTEMPT TO SIMULATE BILIARY ATRESIA. (E.) Morgan, W. W., Jr. (U. Colorado Med. Ctr., Denver), J. G. Rosenkrantz and R. B. Hill, Jr. J. Pediat. Surg. 1(4):342-346, 1966.

14 live-born rabbits in which the porta hepatis was exposed and the hepatic artery divided between gastroduodenal and minor hepatic arteries on day 25 of gestation to cause fetal ischemia which might simulate biliary atresia, 5 showed an absence or hypoplasia of the intrahepatic bile ductules. However, the changes in these 5 rabbits were not uniform throughout the liver; often the structure differed in each lobe. In 2 other experimental animals, the histologic picture was characteristic of coccidiosis. In no instance was there evidence of the hepatic necrosis typically seen after ligation of the hepatic artery in the adult rabbit. A normal liver histologic picture was seen in 5 rabbits after arterial division, 1 animal after laparotomy alone and in 3 rabbits which did not undergo fetal operations. The mortality rate in this experiment was high: of 69 fetuses operated on for arterial interruption and 8 which were subjected to laparotomy only, only 14 of the experimental animals and 1 of the sham-operated animals survived.

- 1838 THE MYCOLOGY OF BILE AND THE GALLBLADDER. IV. THE MODE OF ENTRANCE OF FUNGI INTO THE GALLBLADDER. (Ger.) Hermanek, P. (Vienna General Polyclinic, Austria). Acta Hepatosplen. (Stuttgart) 13(4):208-227, 1966.
- Appearance of Candida albicans and its route of entry into bile and gallbladder of healthy adult (3-4 kg) rabbits was investigated after i.v. admin. of 0.7 ml/kg yeast culture and performing mycologic and histologic studies on animals sacrificed at 6, 24, 48, 72 hr, and on 1 rabbit at 5 days (spontaneous death). The C. albicans was cultured (after previous i.p. rabbit passage) on Sabouraud liquid medium at 5°C/24 hr., followed by incubation at room temperature for 24 hr. Four rabbits were sacrificed without having been infected (controls). No systemic infection, nor presence of yeast in organs was seen, even though these animals hosted C. albicans in the lower intestinal tract. Six hr. after i.v. inj., C. albicans was present in the gallbladder, gallbladder wall, liver, spleen, and heart blood. It disappeared from the blood after 24 hr., from the spleen after 48 hr., from the bile (gallbladder) after 72 hr., prevailing only in the wall of the gallbladder and in the liver even at 5 days. The animal examined after 5 days also had infected kidneys. To determine whether the organism reached the gallbladder walls through the ducts or through the arterial circulation, a portion of the gallbladder fundus was separated by ligation from the rest of the bladder in several rabbits. That separation of the 2 bladder portions was complete was proven by morphologic and histologic observations, by attempts at passage of formalin-methylene blue from one portion to the other and by X-ray studies done on isolated systems made up of liver, gallbladder (divided by ligation as mentioned above), common duct, duodenum and stomach with all the interconnecting blood vessels and major blood supply routes. Contrast fillings into either bladder portion left the other unaffected. Moreover, no visualization of intrahepatic biliary routes could be achieved by injecting the ligated fundus portion of the bladder. Infection (as above) of rabbits thus prepared showed after 12 and 24 hr. the presence of C. albicans in the walls of both bladder portions and in the liver and bile contained in the communicating portion of the gallbladder. The experiments proved conclusively that fungus infections of the biliary tract in rabbits can occur just as frequently through noncanalicular routes, through the circulation, as by the duct system. This is also supported by histologic studies on the gallbladder walls of 56 patients where the presence of fungi in the biliary system was demonstrated. In 30 cases (53.6%) the organisms were localized more or less uniformly in all layers. In 20 cases (35.7%) the organisms were found mainly in the subserosa, and in 6 cases (10.7%) exclusively in the subserosa. In no case was the organism found exclusively, or even substantially in the bladder mucosa.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

11839 THE INFLUENCE ON THE GALLBLADDER OF VAGOTOMY FOR ULCEROUS DISEASES.

(Fr.) Lagache, G. (City Hosp., Lille, France), F. Leplat, B. Combemale and C. Proye. *Ann. Chir.* 20(9-10):607-617, 1966.

Among 113 patients who had undergone bilateral transthoracic vagotomy alone (10 cases) or in conjunction with one or another operative technic for gastric or duodenal ulcer (103), 62 or 55% had normal gallbladders and biliary ducts. Of the 51 with biliary difficulties, 24 had subnormal bladders, 12 had frank biliary abnormalities. Particulars were lacking or incomplete in 15 cases. This information was collected over a period of 15 yr. The great difficulty in a work such as this was the impossibility of establishing a definite causal relationship between the vagotomy and any changes transpiring in the biliary tract. Aside from frequent functional changes observed (enlarged gallbladder with atony) gallstones not existing previously were found in 2 instances.

11840 THE COMMON DUCT AFTER CHOLECYSTECTOMY. INITIAL REPORT OF A TEN-YEAR STUDY. (E.) Hughes, J. (St. Luke's Hosp. Ctr., New York), S. B. Lo Curcio, R. Edmunds and N. Finby. *J.A.M.A.* 197(4):247-249, 1966.

Studies were made on 81 patients after cholecystectomy in a follow-up program in which postoperative cholangiograms were obtained periodically on the same patient. Some of these patients were closely followed up for 3½ yr. In 15 of these patients the preoperative diameter of the bile duct was known. In all patients in this series the common bile duct was measured shortly after patients recovered from surgery and at varying intervals following cholecystectomy. In each case surgery was performed for chronic or acute cholecystitis with or without cholelithiasis. There were no postoperative complications in this group. Cholangiography was performed obtaining laminograms for sharp delineation. Measurement of the diameter of the bile duct was made to the nearest mm with the standardized equipment and procedure to be used throughout this program. The preoperative diameter of the bile duct (15 cases) had not changed when postoperative measurements were made. There was no change in the diameter of the duct in 50 patients with early and late postoperative studies. Among 31 patients some showed increase in duct diameter and others a decrease; for most of these cases the net change was only 1 mm; the greatest net change was 3 mm. In the 81 patients the av. size of the duct postoperatively was 7.4 mm. Complete relief of preoperative abdominal complaints was reported by 67 patients; 14 experienced only partial relief. There was no relationship between the postoperative diameter of the common duct and the relief of symptoms. From the results so far in this program it would appear that the non-pathologic bile duct does not enlarge following cholecystectomy.

11841 THE FAMILIAL OCCURRENCE OF GALLSTONE DISEASE. II. OCCURRENCE IN HUSBANDS AND WIVES. (E.) Van Der Linden, W. (Central Hosp., Osterson, Sweden) and N. Westlin. *Acta Genet. (Basel)* 16(4):377-382, 1966.

A familial case clustering which matched 92 brothers with gallstone disease (verified radiologically or at operation) and their wives against brothers without history of gallstone disease and their wives indicated that, if environmental factors are important for the development of gallstone disease, they are factors which are not shared by husband and wife. In these comparisons, 12 patients' wives suffered, or had suffered, from gallstone disease, whereas the sister-in-law chosen for comparison had not. In 12 other comparisons the opposite was the case. In 2 comparisons both the patients' wife and the sister-in-law had gallstone disease, while in the remaining 65 matches, neither the patients' wife nor the sister-in-law had had gallstone disease. The mean age of the patients was 56 yr., that of the wives, 52 yr., and the sisters-in-law, 51 yr. The patients' marriages had lasted on the av. of 26 yr., while their brothers had been married for an av. of 24 yr. Other possible etiologic factors are discussed.

11842 CHOLESTEROL-HOLDING CAPACITY OF BILE IN RELATION TO GALLSTONE FORMATION. (E.) Nakayama, F. (Kyushu Fac. Med., Fukuoka, Japan). *Clin. Chim. Acta* 14(2):171-176, 1966.

A method for the determination of additional cholesterol-holding capacity of bile (which requires as little as 0.5 ml of bile) is presented using gallbladder bile

from 12 humans, 6 oxen and 10 dogs. Additional cholesterol-holding capacity of bile is defined as the amount of cholesterol which can be solubilized in addition to the cholesterol originally present in the bile. It is expressed in mg% representing the difference in cholesterol conc. before and after solubilization of 2.0 added cholesterol. A species difference was seen in the additional cholesterol-holding capacity of bile: in the dog, it was approx. 170 mg%, in the ox 160 mg% and in man 70 mg%. Lowering the temperature below 37°C depressed cholesterol uptake; ox gallbladder bile at 37°C took up as much as 100% more cholesterol than at 25°C, while with dog bile the difference was 20%. The max. cholesterol-holding capacity of bile decreased with dilution; at first the decrease was slight, but with further dilution the capacity decreased rapidly. In all species, the total amount of cholesterol which can be solubilized was roughly proportional to the amount of bile acids and phospholipids present in bile. When bile protein was removed from the bile, or when the bile samples were heated at 100°C for 30 min., the additional cholesterol-holding capacity was not changed.

43 PARTIAL AND INTERMITTENT BILIARY TRACT OBSTRUCTION RESPONSE OF SERUM BILIRUBIN AND ALKALINE PHOSPHATASE IN DOGS. (E.) Williams, R. D. (U. Texas Med. Branch, Galveston). *Am. Surg.* 32(7):479-482, 1966.

Intermittent biliary obstruction was attempted in 22 mongrel dogs (32-48 kg). Artificial stones were placed in the gallbladder of 16 and in the common bile duct of 6. The simulated stones were either small metal "shot" or lighter barium-sulfate mixture pellets 2-3.5 mm in diameter. The latter were developed because they more nearly simulated the natural stones. In the 6 animals receiving these "stones" directly into the common bile duct, the gallbladder had been removed several weeks earlier; the common bile duct had increased from 3.5 to 4.0 mm in diameter. All stones were sterilized and inserted under anesthesia. In 12 other dogs partial obstruction was produced by probe ligation, a technic developed after considerable experimentation; probe ligation was accomplished by tying 2 ligatures tightly but firmly 5 cm apart on the supraduodenal portion of the common bile duct with a 12-cm long silver probe, 2 mm in diameter, inserted into the common bile duct; following ligation the silver probe was withdrawn and the duodenum closed. This method resulted in an acute complete obstruction followed by a period of partial obstruction. Alkaline phosphatase serum levels and serum levels of bilirubin served as indicators of the degree of obstruction. The artificial gallstones passed readily, remained without producing significant obstruction, or obstructed intermittently. The common duct dilated in relation to the degree of obstruction produced. Partial obstruction was marked by an initial rise in alkaline phosphatase followed by progressive decrease in serum conc. of this enzyme. Complete obstruction resulted in marked ductal dilatation which was maintained after partial obstruction disappeared. The rise in serum alkaline phosphatase usually occurred before jaundice appeared. Increase in serum alkaline phosphatase could be of diagnostic help in suspected common duct stones or other lesions producing partial obstruction without jaundice.

44 THE VALUE OF PRIMARY PREOPERATIVE CHOLANGIOGRAPHY IN DISEASES OF THE BILIARY TRACT. A 2-YEAR STUDY ON OPERATED PATIENTS. (E.) Jørgensen, F. (Aarhus City Hosp., Denmark) and K. Müller. *Danish Med. Bull.* 13(3):58-64, 1966.

A total of 365 patients, operated on during the 2-yr. period from Jan. 1, 1958 to Dec. 31, 1959, were found during operation to have had the following: (1) gallbladder stones (262 cases), (2) stones in the deeper biliary tract (89 cases) and (3) other diseases of the biliary tract (14 cases). These individuals were followed up, interviewed, and examined 2 yr. after operation in order to check for conditions against the original diagnosis and to compare these diagnoses with the findings of the preoperative cholangiographies. The clinical criteria originally used on these patients as an indication for choledochotomy were: (1) jaundice in the course of the attack (on admission or prior to admission). (2) steatorrhea during the course of the disease. (3) Small stones in the gallbladder larger than 3 mm in diameter; this includes "gravel". (4) An increase in width of the choledochus as could be seen by the naked eye during operation. (5)

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

Cholecystectomy previously done. The cholangiographic criteria were: (1) suspected stone shadow, (2) suspected tumor or stenosis, (3) choledochus hepaticus communis equal to or greater than 10 mm in diameter. The possible results from (a) relying on the clinical data alone, (b) relying on the peroperative cholangiography alone, or (c) using both sets of data, are startling. By basing the judgment entirely on the cholangiographic criteria alone 75 superfluous choledochotomies would have been performed and 2 pathologic cases overlooked, whereas judgment based entirely on the clinical criteria would have caused 109 superfluous choledochotomies and neglect of 11 pathological cases. By adding the clinical to the cholangiographic indications the 2 remaining pathological cases would have been found, but at the expense of 139 superfluous choledochotomies.

- 11845 ANTIBODIES TO BILE DUCTS IN THE POSTHEPATIC SYNDROME. (E.) Hořejší, J. (Inst. Hematol. Blood Transfusion, Prague, Czech.) and Z. Ježková. T. Gastroent. 19(3):259-264, 1966.

Serological examination was performed on a control group of 29 patients (healthy or with nonhepatobiliary disease) and 59 patients with posthepatic disorder, subdivided into patients with predominant liver disease (33) and patients with gallbladder disorders (26), with or without clinical findings. Positive antibody to liver, gallbladder and bile duct antigen was noted in cases of hepatobiliary diseases the incidence of serum bile duct antibody was also increased, but without a correlation between the presence of these antibodies and increased serum cholesterol level (above 220 mg%), but not with an increased serum alkaline phosphatase activity. The complement consumption test was negative in all 29 controls. The relatively high incidence of antibodies to bile ducts suggests that the immunological process developed in bile duct elements.

- 11846 CHOLECYSTITIS IN GUINEA PIGS FOLLOWING OPIUM. (E.) Goldstein, H. B. (Walter Reed Army Inst. Res., Washington, D. C.). Am. J. Path. 49(3):491-499, 1966.

Adult guinea pigs were given tincture of opium (1.0 ml, containing 10 mg/ml of morphine i.p.) in 3 experiments: I, the acute experiment, 30 animals were sacrificed 24 hr. after receiving a single inj.; II, 2 groups (4 animals each) were sacrificed after 8 and 18 hr., resp., and 5 were sacrificed 72 hr. after a single inj.; and III, 10 guinea pigs were treated with 1.0 ml every 48 hr., 2 were sacrificed 24 hr. after the second dose and 8 were sacrificed 3 days after 5 inj. were admin. Acute cholecystitis was produced in 80% of the animals within 24 hr. after opium admin. in Group I. Occasional Rokitansky-Aschoff sinuses were found, but no gallstones or bacterial infection of the gallbladder were seen. Repeated inj. of opium caused edema of the lamina propria and severe muscular hypertrophy. The muscularis became 4-5 times thicker than normal in those receiving 5 doses of opium. It is hypothesized that the inflammatory changes were due to spasm of the sphincter of Oddi with resultant obstruction and stasis.

- 11847 GROWTH OF GALLSTONES. (E.) Newman, H. F. (Union Health Ctr., New York, N. Y.) and J. Northup. Pacif. Med. Surg. 74(4):211-215, 1966.

Of 3,500 cases of gallbladder disease, 100 had gallstones. Within an av. of 56.4 mo., the gallstones increased 10% or more in diameter in 30% of these 100 cases. New stones appeared in 17% of these cases, and in 19% of patients who had shown no gallstones initially. In the 30 cases with growing gallstones, there were 2 who apparently passed several stones, and 1 patient in whom 5 radiolucent calculi were later converted to multiple, irregular fragments. In the 70 cases without signs of growth of stones, there were 2 cases in which several stones disappeared; 1 patient showed 5 radiolucent calculi that were later converted to 2 radiopaque stones, and in 1 patient, 5 radiolucent stones were later replaced by debris. In one patient, 7 radiolucent stones tripled in diameter within 71 mo. The nature of gallstone growth is discussed.

- 11848 DISSOLUTION OF HUMAN GALLSTONE IN THE DOG'S GALLBLADDER AFTER VARIOUS DEGREES OF VAGOTOMY. (E.) Barnett, W. O. (U. Mississippi Med. Ctr., Jackson, Miss.) and G. R. Hilbun. Surgery 60(4):840-843, 1966.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

Single human gallstones were placed within the gallbladder lumen of 15 normal dogs. In 5 animals undergoing no alteration of the vagus nerves, 3 animals showed reduction of the stones to 25-30% of their original size at sacrifice 2 wk. later; the stones had completely dissolved and disappeared in the other 2 dogs. Following total abdominal anterior vagotomy and Heineke-Mikulicz pyloroplasty (5 dogs), none of the stones disappeared, and all were 75-100% of the original size after 2 wk. In all branches of the anterior vagus nerve were divided except that supplying the biliary tract (5 dogs), the stones behaved similarly to those of the first group; in 2 animals the stones disappeared completely, while stones from the other dogs showed a 70-75% decrease in size. These results support the concept of biliary stasis after vagal denervation, which may be related to gallstone formation in man.

- 849 ETIOLOGY AND DIAGNOSIS OF PORCELAIN GALLBLADDER. (Ger.) Unglaube, H. L. (U. Surg. Clin., Greifswald, Germany). Deutsch. Gesundh. 21(36):1707-1710, 1966.

Three cases are presented in a review of the condition of the gallbladder characterized by hydropexic enlargement with a shell-like, chalk-layered, fibrotic wall. The X-ray picture is striking but must not be confused with that of the liver affected with echinococcus. Inflammation is considered an important factor in the etiology of this condition; other factors are newly formed glands in the mucous membrane, insufficiency of lymph drainage due to inflammation, and intermittent occlusion of the ductus cysticus with water absorption through the bladder wall and precipitation of calcium carbonate. The diagnosis of "porcelain gallbladder" should only be made after very careful examination; i.v. cholangiography with layered radiographs offers the best protection against diagnostic errors. The peculiar conditions found in this pathology are emphasized by examples from the 3 cases reported. The gallbladders all showed fibrosed walls as well as the chalky deposit; the specimen bladder contained a fluid which was milky due to suspended particles of lime; the fluid in another patient was dark, and the third specimen contained green bile.

- 850 PHYSIOPATHOLOGY OF THE BILIARY TRACT AND PATHOGENESIS OF DISORDERS AFFECTING IT. (It.) Nuvoli, U. Riforma Med. (Napoli) 80(18):477-492, 1966.

A study of 1,000 X-ray records of patients with disorders of the biliary tract and related structures, supplemented by analysis of 500 additional surgical records, concludes that the presence of gallstones is a result, rather than the cause, of a nonspecific, functional disorder characterized by chronic biliary stasis secondary to persistent spasm of the sphincter of Oddi and/or of the large hepatic ducts. The same condition is held to be responsible for a wide range of cholangiopathies and related liver disorders, including inflammatory disorders of the biliary tract and hepatic colic, which has been shown to involve intermittent, violent spastic contractions of the entire system of bile ducts. A similar functional disorder appears to be responsible for the formation of calculi in the urogenital tract, with spasms accompanied by intermittent or prolonged occlusion of the ureter and the stones themselves, as in the case of gallstones, playing a relatively minor role in the genesis of the pain syndrome.

- 851 IMMEDIATE EFFECTS OF INSTRUMENTAL DILATATION OF THE AMPULLA OF VATER. VISUAL AND HISTOLOGIC OBSERVATIONS IN MAN. (E.) Reynolds, B. M. (Misericordia Hosp., New York). Ann. Surg. 164(2):271-274, 1966.

Six patients subjected to choledochotomy, longitudinal duodenotomy (in the second portion of the duodenum) was performed for direct visualization of the immediate effects of instrumental dilatation of the ampulla of Vater. In all cases considerable and obvious anatomical disruptions (to the sphincter of Oddi) were caused by the use of from #4-#6 dilators: longitudinal tears, varying from 2-14 mm and an intense edema with gross reddening of the mucosa was seen in all instances. Biopsy after the ampullary dilatation showed extensive hemorrhage in the submucosal area of the ampulla in all specimens. This study suggests that instrumentation of the ampullary orifice should not be performed with anything greater than a #3 Bakes

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

dilator. Furthermore, to assure patency of the choledochus, passage of a ureteral catheter is safer and usually suffices for this purpose as well as sufficiently aiding in palpation of the interpancreatic and peripancreatic choledochus and ampullary area. Operative cholangiography further obviates the need for instrumentation.

- 11852 OBSERVATIONS ON THE PATHOGENESIS OF GALLSTONES. (E.) Lorentz, T. G. (U. Witwatersrand and Johannesburg Gen. Hosp., South Africa). Brit. J. Surg. 53(6):503-509, 1966.

No calculi were found in 300 gallbladders taken from the common vervet monkey (Cercopithecus ethiops), but in 10% the gallbladders appeared both macroscopically and histologically abnormal. In these 10% inflammation was evident and a good correlation was found between positive bacterial cultures and poor pathology. The biochemistry of the bile led to the suggestion that the critical ratio of cholesterol solvents/cholesterol remained high enough to prevent precipitation, despite the inflammation and stasis. When 170 Syrian hamsters were fed a lithogenic diet, 68% of them developed gallstones, whereas mystromys (closely related to the hamster and having same anatomical arrangement of the biliary tree) fed the same diet did not. The gallbladder histology in both the experimental and control groups of both animals did not differ from normal. Thus, in hamsters, a lithogenic diet can lower the bile-salt/cholesterol ratio to a point where the cholesterol precipitates even in a normal gallbladder. In the third part of this study, gallbladder bile was analyzed at autopsy of 12 whites and 12 African negroes and the following values were found to be consistently higher in the African negroes: bile-salt/cholesterol ratio, the glyco-conjugates/tauro-conjugates ratio and the phospholipid conc. These facts partially explain why gallstone disease has a greater incidence in the white races.

- 11853 PROVOCATION OF SERUM ENZYME ACTIVITY IN CHOLECYSTECTOMIZED PATIENTS GIVEN OPIATES. (E.) Burckhardt, D. (Mem. Hosp. Cancer Allied Diseases, New York, N. Y.) and J. S. Ladue. Am. J. Gastroent. 46(1):43-50, 1966.

Following i.m. inj. of morphine or meperidine, all 3 patients presented in this paper, who had undergone previous cholecystectomies, developed increased activity of serum glutamic-oxaloacetic transaminase (SGOT). Furthermore, in 2 patients an elevation of serum lactic-dehydrogenase (SLDH) and serum α -hydroxybutyric dehydrogenase (SBDH) also occurred after these inj. The creatine phosphokinase (CPK) activity remained within limits except during the one incidence of myocardial infarction. The 71-yr.-old man in which this occurred later showed increased SGOT, SLDH and SBDH activity following inj. with meperidine without a rise in the CPK activity. On this occasion, the electrocardiogram did not change. Another patient a 52-yr.-old woman, suffered severe epigastric pain which radiated substernally, along with a significant rise in SGOT activity, 12 hr. after i.m. inj. with morphine sulfate. A second inj. was associated with similar distress (but which developed in 20 min.) and was followed by the same changes in the SGOT level. A third patient a 73-yr.-old man with hypertensive cardiovascular disease, experienced slight epigastric discomfort immediately after i.m. inj. with morphine sulfate which was followed by a rise in SGOT, as well as a minor elevation in SLDH and SBDH.

- 11854 GAS IN GALLSTONES: A RARE RADIOLOGICAL SIGN IN THE ACUTE ABDOMEN. (E.) Hay, H. R. C. (Orpington, Sevenoaks, Tunbridge Wells Hosp., England). Gut 7(4):415-419, 1966.

Preoperative abdominal X-ray films in 2 women with gallbladder disease showed triradiate gas shadows diagnostic of gallstones. Cholecystography and i.v. Biligrafin films of the first case showed persistent shadows which had rotated since routine plain, supine and erect films had been taken. Following cholecystectomy the gallstones were radiographed, and a clear triradiate sign was noted. The stones were placed in a liquid paraffin-containing vessel, then punctured, and gas bubbles were observed rising through the oil from the stones; X-ray examination and tomograms confirmed the presence of these 'Mercedes-Benz' shadows in the gallbladder crevices. A review of the literature showed that these gas shadows occur only in acute cholecystitis. Due to the constant extraction of the fluid from the bile by

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

he gallbladder, even from the gallstones, the dry central portions of the stones could crack and be filled with oxygen-poor air produced by abnormal contractions of the sphincter of Oddi. Several other processes to explain the presence of these gas-containing biliary calculi are discussed. The author believes that the rare occurrence of all the processes coincidentally in one patient accounts for the infrequent incidence of the "Mercedes-Benz" sign.

- 1855 STUDY OF THE EXCRETION IN BILE AND CONCENTRATION IN THE GALLBLADDER WALL OF RIFAMIDE. (E.) Acocella, G. (Maggiore Hosp., Milan, Italy), F. Lamarina, L. T. Tenconi and F. B. Nicolis. Gut 7(4):380-386, 1966.
- Our subjects with biliary drainage (7 days after cholecystectomy) were treated with rifamycin B diethylamide (rifamide; 150 mg i.m. every 8 hr. for 24 hr.); bile was collected during and after treatment, and rifamide, bilirubin and cholesterol levels determined. The conc. of rifamide in the gallbladder was determined in 16 patients treated with rifamide (150 mg i.m. every 8 hr.) for 1-8 days prior to cholecystectomy. Peak rifamide conc. of 1100-2400 $\mu\text{g/ml}$ appeared in bile 3-4 hr. after inj.; the conc. fell to 8 $\mu\text{g/ml}$ after 32 hr. Bile output ranged from 11.5-25 ml/hr. during this period. Bilirubin excretion was from 45.3-120.3 mg/100 ml during treatment with rifamide and 52.2-134 mg/100 ml in control periods; cumulative excretion was 8.5-14.3 mg/hr. during rifamide treatment and 10.9-15 mg/hr. in the control period. Cholesterol conc. in bile was 21.1-69.1 mg/100 ml during treatment, and 6.9-92.6 mg in control periods. The gallbladder contained 140-972 $\mu\text{g/organ}$ of rifamide in the second group of patients; there was no evidence that conc. in the gallbladder wall was affected by the duration of treatment. Total recovery of rifamide in bile was 55-57% of the dose. With the therapeutic dose, the conc. of rifamycin in excreted bile was 100,000 times its minimal inhibitory conc. in vitro for Gram-positive organisms (0.02-0.1 $\mu\text{g/ml}$) and about 100 times that for Gram-negative organisms (about 20 $\mu\text{g/ml}$). It is concluded that rifamycin can be used for clinical gallbladder infections, especially of Gram-positive origin.

SUBJECT INDEX

Numbers followed by an asterisk (*) refer to abstracts in the text. Other numbers refer to citations only.

ABDOMEN

acute: 11141,11147
 diagnosis: 11005*,11046*,11854*
 ascites (see also Cirrhosis, peritoneum):
 11545
 diagnostic methods: 11023
 pain: 11023
 surgery: 11018
 ABSORPTION: 10803*,10820*,10836*,11001*
 carbohydrate: 10825*,10826*,10829*
 glucose: 10828*
 sucrose: 10809*
 cholesterol: 10804*
 drug: 10815*,10841
 fat: 10825*
 lipids: 10804*,10807*,10825*,10839
 protein
 amino acids: 10811*,10835*
 thiamine: 10802*
 trace elements and minerals: 10801*,10822*,
 10834*
 calcium: 10801*,10817*,10818*,10823*,
 10827*,10831*,10833*,10834*
 copper: 18222*
 iron: 10805*,10806*,10812*,10818*,10822*,
 10830*,10837*,11194*
 strontium: 10806*,10823*,10831*
 vitamins: 10808*
 C: 10813*
 thiamine: 10802*
 water and electrolytes: 10824*
 potassium: 10820*
 sodium: 10810*
 ACHALASIA: 11150*
 ADHESIONS: 10998*,11054*
 AEROPHAGIA (see Gas)
 AGING, effect of: 10810*,10967,10974,11621*,
 11922
 ALBUMIN (See Liver, plasma proteins)
 ALCOHOL (see also Cirrhosis; Liver, fatty,
 Pancreatitis): 11581*,11585*,11596*,11745*
 ALKALINE PHOSPHATASE (see Phosphatase)
 ALLERGY (see Immunology)
 AMEBIASIS
 epidemiology: 11049*
 liver: 11614*,11662
 treatment: 11013,11029*,11614*
 AMMONIA (see Liver)
 AMYLASE (see also Pancreas): 10772*,10877,10886*,
 10955*,11022
 AMYLOIDOSIS: 11128,11307,11389
 ANEMIA (see also Cirrhosis; Malabsorption, treat-
 ment, vitamin B12; Folic Acid; Malabsorption,
 iron; Liver, diseases): 10812*,11404*,11419,
 11743*
 ANEURYSMS: 11680,11686
 ANOREXIA NERVOSA: 11094
 ANTACIDS: 10883
 ANTIBIOTICS: 10807*,10818*,10830*,10978,11012,
 11035*,11037*,11042*,11056,11183*,11184*,
 11615*,11672,11723*,11855*,11915,11945,11947,
 11951

ANTISPASMODICS: 10841,11021,11061
 ANUS

anomalies: 11442,11449
 cancer: 11469
 diseases: 11445,11448
 pruritus ani: 11430*
 sphincters: 11460,11486
 surgery: 11460,11486
 AORTOGRAPHY (see Gastrointestinal tract,
 diagnosis)
 APPENDICITIS: 11426*,11431*,11455,11456,11462,
 APPENDIX: 11088,11454,11457
 ASCITES (see Abdomen, ascites; Cirrhosis, ascit
 ATHEROSCLEROSIS (see associated diseases under
 each organ): 11342*,11663

BACTERIA (see Microorganisms)

BILE: 11917
 composition: 10934*,10954*,10981,11852*
 digestive action: 10806*,10807*,10833*,1084
 secretion: 10806*,10845*,10884,10935*,10936
 10944*,10949*,10977,10978,11857
 BILE ACIDS AND SALTS (see under Absorption)
 BILE DUCT (see Biliary Tract)
 BILE PIGMENTS: 11658
 BILIARY TRACT (see also Gallbladder)

Ampulla of Vater: 11851*,11865,11866,11886
 anomalies: 11837*,11887,11894,11949,11957
 associated diseases: 11323,11924,11938
 cancer: 11867,11884,11905
 cholangiography: 11859,11860,11866,11880,11
 11886,11903,11910,11911,11923,11925,11944
 11958
 common duct: 11577*,11712,11725*,11760,1184

 11898,11930,11948,11952,11955
 development: 11837*
 diagnosis: 11656,11861,11870,11952
 cholangiography: 11844*
 diseases (see also under Cholecystitis;
 Cholelithiasis): 11628,11838*,11856,1188
 11889,11892,11900,11904,11915,11918,11928
 11929,11936,11937,11938,11941,11947,11951
 11956,11960,11961
 fistula: 11919,11921,11948
 hemobilia: 11659,11890,11927
 morphology: 10778*,11924
 motility: 11856
 pressure: 10845*
 obstruction: 11607*,11608*
 Papilla of Vater: 11905,11926
 physiology: 11874
 Sphincter of Oddi: 10845*,11846*,11850*,
 11851*,11875,11893,11950,11953
 stricture: 11725*,11843*,11865,11897,11898,
 11926,11930,11950
 structure: 11873
 surgery: 11577*,11844*,11858,11864,11875,
 11878,11887,11888,11893,11901,11906,11907,
 11922,11948,11953,11956
 BILIRUBIN: 10935*,10970,11607*,11626*,11788*,
 11808*,11843*,11855*

OPSY (see Diagnosis under individual organs)
EEDING (see also Ulcer, Peptic): 10830*,11062,
11067,11146,11214,11277,11298,11343*,11387,
11389,11390,11801
diagnosis: 11003*,11027*,11140
treatment: 11075,11484,11501
surgery: 11044*
OOD COAGULATION (see also under Cirrhosis)
liver disease: 11623*,11627*,11729*,11742*
OOD GROUPS (see under Genetic Relationships)
ADYKININ: 10899*
DD-CHIARI SYNDROME (under Liver): 11629,
11634,11692
NCER (see also under individual organs): 11114,
11134
diagnosis: 11587*
etiology: 11403*
gastric stump: 11265
treatment
chemotherapy: 11619*,11690
radiation: 11169,11690
RCINOGENESIS (see also specific organ)
RCINOID SYNDROME; CARCINOIDS (see also
Serotonin): 11054*,11107,11362
RDIOSPASM (see Achalasia)
RDIOVASCULAR SYSTEM (see also under individual
organs and Portal Hypertension)
THARTICS (see Laxatives)
CUM (see also Intestine, Large): 11436,11464,
11468,11497,11503
LIAC DISEASE (see Malabsorption)
NTRAL NERVOUS SYSTEM (see also under individual
organs; Neuroendocrine Control): 10765*,10774,
10794,10797,10798,10901*,10916,11020,11023,
11182*,11467,11600*,11756*
OLANGIOGRAPHY (see under Biliary Tract)
OLE- (words beginning with: see below and under
Gallbladder; Biliary Tract and Bile)
LECYSTITIS: 10934*,10954*,11260,11844*,11846*,
11847*,11852*,11854*,11872,11877,11878,11883,
11890,11895,11907,11909,11920,11939,11947,
11952,11954,11960
OLECYSTOGRAPHY (see Gallbladder, diagnosis)
OLELITHIASIS: 11524*,11642,11712,11841*,11842*,
11843*,11848*,11850*,11852*,11854*,11857,11868,
11871,11879,11885,11899,11902,11906,11916,
11922,11933,11934,11943,11945
OLERA: 10765*,11092,11127,11132
OLESTASIS: 11582*,11600*,11607*,11608*,11677,
11679,11771,11779,11850*,11914,11931
OLESTEROL (see Absorption; Liver, metabolism,
cholesterol and steroid): 10892*,11186*,
11842*,11874
RRHOSIS (see also Abdomen, ascites; Esophageal
Varices; Hepatic Coma; Liver, alcohol;
Portal Hypertension): 11677
anemia: 11817*,11818*,11829*
ascites: 11820*,11828*,11832*,11835
associated diseases: 11036*,11148*,11151*,
11170,11340*,11366,11590*,11825*,11826*,
11827*,11834*
blood coagulation: 11836,11829*
diagnosis: 11053*,11592*,11597*
etiology: 11613*,11734*,11822*
experimental studies: 11831*

CIRRHOSIS (Contd.)
metabolic changes: 10868*,11605*,11740*,
11818*,11820*,11824*,11830*
pathology: 11627*,11665,11823*,11826*,11832*,
11833*
treatment: 11821*,11828*,11835
water and electrolyte metabolism: 11819*
COLITIS (see also Enteritis; Enterocolitis;
Gastroenteritis): 11131,11450,11492,11499
COLITIS, GRANULOMATOUS (see Enteritis, regional)
COLITIS, ULCERATIVE (see Ulcerative Colitis)
COLON (see Intestine, large)
CONSTIPATION: 11467
CORTICOSTEROIDS: 10937*,10938*,10993,11355,11564,
11741*,11745*,11756*,11788*,11790*
DIAGNOSTIC PROCEDURES (see under Gastrointestinal
Tract, diagnosis; specific organs and diseases)
DIAPHRAGM (see also Hernia, diaphragmatic)
DIARRHEA: 10997*,11014,11024,11072,11092,11189*,
11409,11421*,11424*,11439,11440,11489,11499
DIET: 11718*
DIETOTHERAPY (see Nutrition)
DIGESTION (see also Bile; Intestine, small;
Pancreas): 10887*,10893*,10959*,10975
lipid: 10807*,10855*,10890*
protein: 10771*,10889*
DUODENUM (see also Intestine, small): 10769*,

diseases (see also under Ulcer): 11030*,
11198*,11293*,11362
diverticula: 11289*
morphology: 10788*,11557*
motility: 10901*,11207*
surgery: 10873*
DYSENTERY (see also Amebiasis; Shigellosis;
Typhoid Fever): 10850*,11056,11136,11439
diagnosis: 11440
epidemiology: 11086,11087
treatment: 11086,11087,11116
EMBRYOLOGY (see Gastrointestinal Tract, development)
EMESIS (see Vomiting)
ENDOSCOPY (see also diagnosis under specific
organ)
ENTERITIS (see also Colitis; Enterocolitis;
Gastroenteritis): 11110,11120
ENTERITIS, REGIONAL: 11379*,11381*,11382,11383,
11384,11385,11389,11386,11387,11388,11390,
Crohn's Disease of colon (granulomatous
colitis): 11380*
ENTEROCOLITIS (see also Colitis; Gastroenteritis):
10839,10850*,11012,11089,11306
ENZYMES, MISCELLANEOUS (see also Amylase; Liver,
enzymes, parenchymal; Pancreas, secretion;
Phosphatase; Stomach, secretion, pepsin):
10814*,10842*
ESOPHAGITIS: 11156*,11161,11164
ESOPHAGUS (see also under Achalasia; Hernia): 11165
anomalies: 11150*,11154*,11158*,11159
associated diseases: 11148*,11151*,11163,
11166,11168,11170
cancer: 11169,11171

ESOPHAGUS (Contd.)

diagnosis: 11011
esophagoscopy: 11019,11173,11175,11177
diseases: 11174,11178
fistula: 11154*,11158,11159
Mallory-Weiss Syndrome: 11153*
morphology: 10798
motility: 10894*,10897*,10903*,11154*,11160
perforation: 11175
prosthesis: 11157,11166
reflux: 11149*
stricture: 11150*,11162,11163,11168
surgery: 11011,11162,11165,11171
varices: 11148*,11151*,11173
FAT (see Absorption, lipid; Digestion; Lipids;
Liver, metabolism; Malabsorption)
FECES: 10767*,11003*,11027*,11439,11531*
FISTULA (see also under individual organs): 11106,
11442,11448,11498,11538

GALLBLADDER (see also Biliary Tract; Cholecystitis;
Cholelithiasis)

associated diseases: 11235,11839*,11853*
cancer: 11863,11891,11935
diagnosis: 11849*,11881
cholecystography: 11670,11908,11913,11917

 reticuloendothelial system: 10942*
 serum proteins: 11576*
 surgery: 11577*, 11646, 11660, 11676, 11697,
 11712, 11935
 transplantation: 10923*, 10924*, 11612*, 11616*,
 11617*
 trauma: 11633, 11683, 11685, 11760, 11761
 vitamin B₁₂ (see also Absorption; Malabsorption;
 Vitamins): 11610*
 LYMPH: 10825*, 10940*, 11070, 11573, 11607*, 11608*,
 11949
 MALABSORPTION (see also Intestine, small;
 Steatorrhea): 11406, 11413
 pathophysiology: 11397*
 anemia: 11419
 disaccharidase deficiency: 11400*, 11407,
 11408, 11410, 11411, 11412, 11420
 intolerance, sugar or milk: 11391*, 11400*,
 11402*, 11409
 vitamin deficiencies: 11419
 primary: 11403*
 celiac disease: 11392*, 11393*, 11397*,
 11405, 11418
 miscellaneous: 11398*, 11399*

LABSORPTION (Contd.)

primary
 sprue: 11392*,11393*,11404*
 tropical sprue: 11401*
 secondary: 11040*,11384,11396*
 diverticulitis: 11289*
 intestinal resection: 11395*
 parasitic infestations: 11414
 treatment
 antibiotics: 11395*,11401*
 dietary: 11402*
 folic acid: 11401*
 vitamin B12: 11401*
 CECAL DIVERTICULUM: 11088,11316,11317,11319,11320
 COLON, CONGENITAL: 11429*,11458,11459,11478,11479,11480,11488
 ENTERY: 10819*
 cancer: 11228
 cyst: 11141
 vascular disease: 11102,11105,11111,11139,11305
 CROORGANISMS (see also Amebiasis; Cholera; Leptospirosis; Salmonellosis; Shigellosis and specific organs): 10775
 in disease: 11026*,11057,11059,11061,11079,11110,11120,11129,11289,11306,11395*,11475,11723*,11838*,11918,11946
 gnotobiosis: 11723*
 normal: 11059
 nutritional changes: 10892*
 TILITY (see also under Smooth Muscle; specific organs): 10915
 pharmacology: 10897*,10898*,10904*,10906*,10907*,10908*,10912,10913,10916,11897
 physiology: 10909,10910,10916,11433
 technics of study: 10895*,10896*
 COVISCIDOSIS: 11541,11547,11522*,11523*,11535
 ENDOCRINE CONTROL (see also Stomach, nervous control): 10832*,10854*,10864*,10867*,10870*,10886*,10916,10984,10985,10990,11341*,11489,11577*,11602*,11750*,11811
 HORMONAL AGENTS:
 acetylcholine: 10877,10904*,10906*,11182*
 epinephrine: 10897*,11741*
 norepinephrine: 10894*,10897*,11820*
 NUCLEIC ACID METABOLISM (see also Liver, metabolism, nucleic acid): 10777*,10816*,10821*
 NUTRITION (see also Absorption; Kwashiorkor; Malabsorption; Vitamins): 10771*,10964,10967,11166,11255,11599*
 dietotherapy: 11652,11667,11707,11727*,11733*
 PANCREAS
 associated diseases: 11524*,11529*
 cancer: 11525*,11529*,11534,11540,11543
 cardiovascular system: 10776,10779*
 circulation: 11526*
 cysts: 11532,11536,11539,11544,11545,11548,11549
 diagnosis
 angiography: 11080,11530*,11533,11537,11543,11552,11546,11550
 enzymes: 11531*

PANCREAS (Contd.)

disease: 11538,11551
 function: 11531*,11542
 metabolism: 10851*
 morphology: 11528*
 pancreozymin: 10851*,11556*
 secretin: 10871*,10872*,11530*,11556*
 secretion: 10851*,10854*,10857*,10871*,10872*,10876
 amylase: 10772*,10866*,10871*,10888*,10955*,11528*
 chymotrypsin: 10860*,11531*
 lipase: 11528*,11555*
 proteolytic enzymes: 10771*
 trypsin: 10860*,10866*,11528*,11531*
 surgery: 11525*,11526*,11527*
 trauma: 11859
 PANCREATITIS: 11567
 acute: 11555*,11562,11563,11564,11565,11566,11569,11570,11574,11575
 pathophysiology: 11046*,11553*,11558*,11572
 associated diseases: 11553*,11556*,11557*,11558*,11565,11567,11575
 chronic: 11556*,11561,11573
 pathophysiology: 11568
 diagnosis: 11554*,11555*,11573
 etiology: 11554*,11571
 experimental: 11558*,11559*,11560*
 treatment: 11562,11564,11569,11570,11574,11878
 PANETH CELLS: 10785*,10788*
 PARASITES AND PARASITIC DISEASES (see also Amebiasis; Schistosomiasis): 11104,11033*,11046*,11078,11093,11702,11904
 associated diseases: 11030*,11414
 experimental studies: 11028*
 pathology: 11028*,11089,11119,11131,11455,11553*,11614*,11638,11659,11885
 treatment: 11064,11076,11122,11125,11137
 PARATYPHOID FEVER (see also Salmonellosis): 11074
 PEPsin (see Stomach, secretion, pepsin)
 PERITONEUM: 11097
 PERITONITIS: 11037*,11103,11142,11274,11862
 PEUTZ-JEGHERS SYNDROME: 11068,11098,11109,11144,11427*
 PHOSPHATASE
 acid: 11736*
 alkaline: 10868*,10967,11582*,11607*,11725*,11736*,11738*,11843*,11954
 PLASMA PROTEINS (see also Liver, plasma proteins)
 POLYPS (see also specific organs; Peutz-Jeghers Syndrome): 11047*,11313,11865
 PORPHYRIA: 11133,11602*,11622*,11711,11752*,11753*
 PORTAL HYPERTENSION: 10773*,11688
 portacaval shunt: 11151*,11293*,11471,11578*,11689,11824*
 treatment: 11699
 PREGNANCY: 10885,10928*,11133,11337,11468,11482,11563,11575,11615*
 PROTEIN-LOSING ENTEROPATHY: 11118
 PROTEIN SYNTHESIS: 10992,11744*
 PYLORIC OBSTRUCTION: 11191*,11196*,11224,11237,11240,11244,11276
 RECTUM (see also Hemorrhoids; Intestine, Large, diagnosis, proctosigmoidoscopy; Polyps; Ulcerative Colitis): 10835*
 anomalies: 11442,11449,11480

RECTUM (Contd.)

associated diseases: 11452,11510*,11519,11521
benign tumors: 11422*,11424*,11437
cancer: 11441,11482,11487,11493,11500
diagnosis: 11440
diseases: 11422*,11443,11445,11475,11501
surgery: 11461,11487,11493

SALIVA: 10842*,10843*,10863*,10885

SALIVARY GLANDS: 10899*

benign tumors: 11115*

cancer: 11052*

diseases: 11057,11058,11079,11081,11121

mixed tumors: 11113

morphology: 10800,10877

secretion: 10843*,10846*,10863*,10864*,10772*,
10877*,10878,10881,10885,10891*

surgery: 11069

tumors: 11069,11085

SALMONELLOSIS (see also Paratyphoid Fever;

Typhoid Fever): 11077

epidemiology: 11042*,11043*

experimental studies: 10766*,11038*,11050*

treatment: 11042*

SCHISTOSOMIASIS: 11078

clinical studies: 11036*,11466,11665

diagnosis: 11041*

treatment: 11000*,11060,11101,11138

SECRETIN (see Pancreas): 10851*

SECRETION (see also Bile, secretion; Pancreas,
secretion; Salivary gland, secretion; Stomach,
secretion): 10838*,10856*,10869*,11007

SEROTONIN (see also Carcinoid Syndrome): 10767*,
10770*,10782*,10900*,10906*,11345*

SHIGELLOSIS (see also Dysentery): 11077,11130,
11145,11451

SHOCK: 11604*,11625*

SIGMOID (see also Intestine, Large): 11424*,
11428*,11432*,11433,11435,11437,11493,11502,
11879

SJÖGREN'S SYNDROME: 11045*

SMOOTH MUSCLE (see also Motility): 10912,

morphology: 10778*

pharmacology: 10914

SPRUE (see also Malabsorption)

STEATORRHEA (see also Malabsorption): 11411,
11206*,11289*

STEROIDS (see also Absorption; Corticosteroids;
Liver, metabolism, cholesterol and steroid):
10849*,10864*,10969,10986,11602*,11341*,
11749*,11779,11785*,11794*

STOMACH (see Bezoar; Gastritis; Pyloric Obstruc-
tion; Ulcer; Volvulus): 10840

absorption: 10836*

anomalies: 11195*,11277

antrum: 10871*,11197*

associated diseases: 11045*,11096,11183*

benign tumors: 11253

cancer: 11053*,11183*,11186*,11210*,11211*,
11218,11219,11223,11225,11228,11236,11243,
11245,11247,11253,11256,11257,11258,11259,
11265,11270,11272,11278,11280,11282

carcinogenesis: 11238,11265

cardiovascular system: 11234,11262,11277

STOMACH (Contd.)

diagnosis: 11002*,11053*,11225,11236,11239,
11256,11271

cytology: 11245,11270,11284

endoscopy: 11019,11173,11227,11230,11269,
11273,11367

gastric analysis: 10852*

radiology: 11198*,11202*,11211*,11216,
11258

diseases: 11030*,11178,11198*,11250,11281,
11283

mucosal injury: 11217,11220,11268

diverticula: 11221,11222

gastrin: 10874

morphology: 10777*,10782*,10784*,10793*,11211

motility: 10887*,10895*,10896*,10901*,10909,
11197*,11209*,11271

mucosa: 11180*,11182*

nervous control: 10774,10847*,10862*,10901*,
11182*,11197*

perforation: 11234

polyps: 11181*,11211*

pyloric reflux: 11207*

radiation injury: 11201*

secretion: 10838*,10845*,10847*,10848*,10852*,
10855*,10856*,10858*,10862*,10879

acid: 10859*,10869*,10871*,10880,10882,

in disease: 10847*,10850*,10868*,10870*,
11045*,11180*,11183*,11187*,11193*

drug effects: 10849*,10859*,10861*,10874,
10875

electrolytes: 10844*

pepsin: 11239

technics of study: 10853*

surgery (see also Gastrectomy): 11228,11229,
11230,11257,11271

gastroenterostomy: 11200*,11219,11335,
11364,11525*

gastroenterostomy and vagotomy: 11354*

gastrostomy: 11195*,11264

pyloroplasty and vagotomy: 11156*,11188*,
11371

vagotomy: 11252,11263

trauma: 11220,11229

SULFOBROMOPHTHALEIN: 10946*,11593*,11594*,11596,
11609*,11729*,11930

SURGICAL APPARATUS: 11011,11264,11858

TRANSPLANTATION (see also Immunology; Liver,
transplantation): 10853*

TRYPSIN (see Pancreas, secretion, proteolytic
enzymes)

TYPHOID FEVER (see also Salmonellosis)

carriers: 11035*

prevention: 11117

treatment: 11035*

ULCER (see also Antacids; Anticholinergics;
Duodenum; Gastrectomy; Intestine, Small,
ulcer, nonspecific)

drug-induced: 11302,11355,11356,11358,11373,
11378

experimental: 10853*,11198*,11343*,11345*

ULCERATIVE COLITIS: 11516,11520

associated diseases: 11521

diagnosis: 11507*,11510*,11515

CERATIVE COLITIS (Contd.)

immune mechanisms: 11512*
 metabolic changes: 11506*,11509*
 pathology: 11507*,11510*,11511*,11519,11521
 psychologic studies: 11517
 treatment: 11514
 medical: 11512*,11513*
 surgical: 11508*,11518
 CER, PEPTIC, GASTRODUODENAL: 11232,11284,
 11344*,11357,11363,11365,11370,
 anastomotic: 11213,11361
 associated diseases: 11163,11340*,11342*,
 11362,11365,11368,11540
 bleeding: 11044*
 clinical studies: 11375,11376
 complications
 bleeding: 11346*,11347*
 perforation: 11360
 diagnosis: 11053*,11202*,11211
 epidemiology: 11348*
 etiology: 10853*,11280,11340*,11341*,11347*,
 11369
 freezing: 11377
 metabolic changes: 11278
 pathology: 11367,11372
 secretion: 11187*,11349*,11350*,11351*

ULCER, PEPTIC, GASTRODUODENAL (Contd.)

11232,11284,11344*,11357,11363,11365,11370
 treatment
 freezing: 10853*,11212,11262,11347*
 medical: 11345*,11374
 surgery: 10847*,11214,11218,11219,11349*,
 11350*,11351*,11352*,11353*,11354*,
 11371,11839*

VITAMINS (see also Absorption; Malabsorption; Liver)

A: 10960*
 B-complex: 10808*,10930*,10931*,10987,11667,
 11652,11707,11713,11714,11720*,11721*,11726*
 B12: 11205*,11707
 C: 10837*,11721*
 D: 10806*,10817*,10818*,10833*,10941*
 E: 10983,11721*
 folic acid: 10816*,10846*,11610*,11707,
 VOLVULUS (see also specific organ): 11088,11452
 VOMITING: 11020,11091,11196*,11197*
 WHIPPLE'S DISEASE: 11394*,11415,11416,11417
 WILSON'S DISEASE (see Hepatolenticular degenera-
 tion)
 ZOLLINGER-ELLISON SYNDROME: 11080,11082,11083,

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. In the abstract issues, approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis and
Metabolic Diseases
National Institutes of Health
Bethesda, Maryland 20014

Special Note for Index Issue

This index for Volume 1 of GASTROENTEROLOGY ABSTRACTS and CITATIONS is primarily a uniterm index with most of the entries being either disease or organ oriented but with some entries with concept orientation. Comments and criticisms from the users of this publication will greatly influence the course of development and improvement in future indexes.
